3rd International DZL Symposium

"Lung Regeneration and Beyond – BREATH meets REBIRTH"

Datum/Ort: 8.–10. Mai 2014, Hannover

Presidents: Prof. Dr. Tobias Welte
Prof. Dr. Dr. Axel Haverich

Editorial

Lungenerkrankungen gehören zu den wesentlichen Erkrankungen weltweit, die WHO erwartet, dass sie in absehbarer Zeit hinsichtlich Morbidität und Letalität die Spitzenposition übernehmen.

Lungenerkrankungen sind entweder proliferative – Bronchialkarzinom, Lungenfibrose, pulmonale Hypertonie – oder degenerative Erkrankungen (COPD, Emphysem). Für einige dieser Erkrankungen konnte eine Verlangsamung der Erkrankungsprogression erreicht werden, kausale Therapieansätze gibt es jedoch nicht. Nur für die Mukoviszidose konnte für eine spezifische Mutation eine Korrektur des Basisdefekts und damit quasi eine Heilung erreicht werden.

Führen chronische Erkrankungen zu einer respiratorischen Insuffizienz bleibt die Lungentransplantation die einzige Option, um das Leben zu verlängern und eine bessere Lebensqualität zu schaffen. Allerdings stehen knapp 400 Lungentransplantationen in Deutschland pro Jahr eine halbe Million „End Stage" Patienten gegenüber, ein krasses Missverhältnis.

Zwei Therapieoptionen könnten Abhilfe schaffen: Die Weiterentwicklung von kurzzeitig einsetzbaren extrakorporalen Unterstützungssystemen zu einem chronischen Organersatz und die Stammzelltherapie zur Korrektur von Gendefekten und zum Ersatz von zerstörtem Geweben. Für beides hat es in den letzten Jahren erste ermutigende Ergebnisse gegeben, allerdings gibt es bei weitem mehr offene Fragen als Antworten.

Das dritte internationale Symposium des Deutschen Zentrums für Lungenforschung (DZL) widmet sich schwerpunktmäßig diesen beiden Themenbereichen. Es fand vom 8. – 10. Mai 2014 am DZL-Standort Hannover in Kooperation mit dem Exzellenzcluster REBIRTH unter dem Thema „Lung Regeneration and Beyond – BREATH meets REBIRTH" statt.

Neben führenden internationalen Wissenschaftlern und Ärzten zum Thema Stammzellen, Organersatz und Transplantation stellten Nachwuchswissenschaftler aus DZL- und REBIRTH ihre Arbeiten in Vorträgen und auf Postern vor. Die Mischung aus internationalen Koryphäen und Nachwuchswissenschaftlern schuf beim Symposium eine besondere Atmosphäre.

Die nachfolgenden Abstracts geben einen Einblick in den aktuellen Stand der wissenschaftlichen Entwicklung in dieses hochaktuelle Forschungsgebiet.

Prof. Dr. Axel Haverich, Sprecher des Exzellenzclusters REBIRTH und Professor Dr. Tobias Welte, Standortdirektor BREATH und Direktor im DZL, beide Klinikdirektoren an der Medizinischen Hochschule Hannover

Disease Area: Asthma & Allergies

1 Species comparison of interleukin-13 induced airway hyperreactivity in precision-cut lung slices

Danov O[1,3], Jimenez Delgado SM[1,3], Drake H[1,3], Schindler S[1], Pfennig O[2], Förster C[2], Braun A[1,3], Sewald K[1,3]
[1]Fraunhofer-Institut für Toxikologie und Experimentelle Medizin, Hannover; [2]KRH Klinikum Oststadt-Heidehaus, Hannover; [3]Biomedical Research in Endstage and Obstructive Lung Disease (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376770

Interleukin-13 is a key cytokine of asthma and elevated in asthmatics resulting in airway hyperresponsiveness (AHR). AHR is a hallmark of allergic asthma defined as exaggerated bronchoconstriction in response to contractile stimuli. Research for the development of new drugs is mainly based on appropriate in vivo and in vitro models. There is a need for translational models with improved predictivity for human. For comparison of different species we used precision-cut lung slices (PCLS) and assessed IL-13 induced hyperreactivity in PCLS of mice, rats, and humans. PCLS were prepared from Balb/c mice, Brown Norway rats, and humans. IL-13 receptor was stained in the airways of mouse, rat and human PCLS by immunohistochemistry. Airways of all species were pre-incubated with 100 ng/mL IL-13. Subsequently, bronchoconstriction was induced by addition of methacholine (MCh) and visualized by videomicroscopy. IL-13 receptor was present in epithelial cells and smooth muscle cells in PCLS of all species. Methacholine-induced bronchoconstriction in mouse exhibited an EC 50 of 80 nM and decreased by pre-incubation with IL-13 to 50 nM, in rat from 220 nM to 170 nM and human from 180 nM to 47 nM MCh. In general, pre-incubation of PCLS in the presence of IL-13 resulted in all species in stronger bronchoconstriction at maximum methacholine concentration. Maximal constriction of initial airway area resulted in mouse in Cmax 61% by control and decreased in IL-13 pre-incubated tissue to 80%, in rat by 49% to 69% and human by 85% to 94% compared to untreated tissue. This study shows that IL-13 receptor is similar distributed in epithelial cells and smooth muscle cells of all three species. IL-13 induced airway hyperreactivity in all tested species with different methacholine sensitivity. In future studies, PCLS will be used for pre-clinical studies to valuate the antagonist efficacy.

2 Deregulation of ORMDL3 expression induces stress responses and modulates repair pathways

Kallsen K[1], Fink C[2], Bhandari A[2], Kabesch M[3,6], Heine H[4], Roeder T[2,5]

DOI: 10.1055/s-0034-1376771

The asthma-susceptibility gene ORMDL3 is an ER transmembrane protein previously associated with sphingolipid metabolism, the unfolded protein response, Ca2+ homeostasis, T-cell activation, and antiviral responses. However, the functional relevance of ORMDL3 in asthma pathogenesis remains elusive. Using the fruit fly Drosophila melanogaster as a model, we mimicked the situation found in patients at risk for asthma by increasing the expression of ormdl, the sole Drosophila homolog of ORMDL3, in the airway epithelium. Although ormdl overexpression did not overtly affect epithelial integrity, it increased the susceptibility to airborne stressors, such as cigarette smoke and hypoxia. When confronted by daily doses of cigarette smoke, flies overexpressing ormdl in the airway epithelia had a significantly shortened lifespan compared to matched controls. Moreover, these animals exhibited a much stronger behavioral response to hypoxia, and signaling systems such as the unfolded protein response and the TOR/PI3K pathway lost their ability to react to this stressor. In addition, overexpression of ormdl in the airways drastically reduced the output of signaling pathways associated with repair mechanisms, including EGFR and Notch signaling. These molecular changes were accompanied by changes in the lipid profile that resembled the situation observed in asthmatic airways. On the basis of these findings, we conclude that ORMDL proteins increase the stress status of the airway epithelium, which increases susceptibility to stress factors and increases the probability of developing asthma.

3 Characterization of lipophilic house dust mite-allergens with regard to the allergic phenotype

Kull S[1,4], Petersen A[1,4], Vrtala S[2], Jappe U[1,3,4]
[1]Research Center Borstel; Division of Clinical and Molecular Allergology, Borstel; [2]Center for Pathophysiology, Infectiology and Immunology, Department of Pathophysiology and Allergy Research, Vienna, Austria; [3]Department of Dermatology and Allergology, University of Luebeck, Luebeck; [4]Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376772

The common causes for respiratory allergies and allergic asthma are house dust mites (HDM). Not all HDM-allergic patients are detected by use of commercially available aqueous HDM-extract. Especially with regard to lipophilic allergens a lot of information is still lacking which is due to their low concentration in the respective extracts or because they are hidden in a complex matrix. However, there is evidence from other allergen sources that lipophilic allergens are associated with severe clinical reactions. For studying these allergens in more detail as probable cause for HDM-asthma and for improving diagnostic tests, lipophilic allergens need to be identified, isolated and characterized in order to determine their allergenic risk. In the case of house dust mite some hydrophobic allergens have already been identified (e.g. Der p 5, 7, 13, and 14). For studying interactions of these allergens with the epithelial cells of the respiratory tract a high amount of purified and well characterized single allergens is needed. Therefore, we started with the expression of recombinant allergens (e.g. Der p 5, 7, and 13) in *E. coli* and *Pichia pastoris*. In parallel, we use sera from patients with different clinical phenotypes for further component-resolved investigations with the recombinant HDM-allergens Der p 1, 2, 4, 5, 7, 10, 11, 14, 15, 18, 21, and 23, applying immunoblot analysis. Up to now 43 sera of which the majority showed an IgE-reactivity against the major allergens Der p 1 and 2, were tested; one patient reacted with Der p 7, five with Der p 5 and one with Der p 21. Future work will focus on the significance of selected hydrophobic HDM-allergens which are associated with allergic asthma. We will address the interaction of the single allergens with epithelial cells, probable receptor activation and cell uptake.

4 Investigating the role of BAFF in different mouse models of allergic asthma

Lorenz A[1,3], Busse M[1], Dalüge K[1], Behrendt AK[2], Hansen G[1,3,], Meyer-Bahlburg A[1,3,*]*
[1]Hannover Medical School, Hannover; [2]Rostock University Medical Center, Rostock; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376773

*equal contribution **Introduction:** The cytokine B cell activating factor of the TNF family (BAFF) is crucial for the homeostatic development, differentiation and proliferation of B cells in the periphery. It is well known that elevated BAFF levels are associated with autoimmune diseases but its role in allergic diseases including asthma is barely understood. **Aims and objectives:** To better comprehend the role of BAFF in allergic asthma we started analyzing BAFF in murine asthma models. **Methods:** Wildtype (WT) and B cell deficient (μMT) mice were immunized with ovalbumin (OVA) or house dust mite (HDM). Bronchoalveolar lavage fluid (BALF) was measured morphometrically, airway hyperreactivity (AHR) by invasive lung function and BAFF via ELISA. **Results:** Asthmatic WT mice showing lung eosinophilia and severe AHR have significantly elevated BAFF serum levels compared to controls. Additionally, in OVA-induced respiratory tolerant mice, BAFF levels are lower than in allergic mice. Kinetic studies demonstrate that BAFF levels increase, the more often allergen is administered intranasally suggesting local BAFF production in the asthmatic lung. Furthermore, BAFF determination in BALF showed increased levels in allergic compared to control mice. To test, whether BAFF is related to elevated IgE levels during asthma, BAFF production in μMT mice was analyzed. Allergen treated μMT mice develop a similar allergic phenotype compared to WT mice and show increased BAFF levels in serum and BALF even in IgE absence.

Conclusions: In asthma models, allergic mice show elevated systemic and local BAFF levels, which increase with the frequency of allergen uptake via the lung and are independent of IgE presence. Thus, BAFF inhibition, recently permitted for treatment of systemic lupus erythematodes, might represent a new therapeutic target in allergic asthma.

5 RORγt-specific RNAi decreases allergic airway inflammation and airway hyperresponsiveness in a mouse model of neutrophilic asthma

Webering S[1,4], Lunding L[2,4], Behrends J[3], Fehrenbach H[1,4], Wegmann M[2,4]
[1]Division of Experimental Pneumology, Priority Area Asthma & Allergy, Research Center Borstel, Borstel; [2]Division of Mouse Models of Asthma, Priority Area Asthma & Allergy, Research Center Borstel, Borstel; [3]Division of Fluorescence Cytometry, Research Center Borstel, Borstel; [4]Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL), Borstel
DOI: 10.1055/s-0034-1376774

Introduction: Recent studies suggest T helper 17 (Th 17) cells as important players in the progression of asthma towards a severe phenotype. Characterized by the production of pro-inflammatory cytokines like TNF-α, IL-1ß, IL-22 and IL-17A, Th 17 cells appear to act as general promoters of chronic inflammatory responses. These effector functions are regulated by the transcription factor Retinoic acid-related Orphan Receptor gamma (RORγ) t, which is essential for their differentiation. Thus, RORγt represents an ideal target not only to investigate the actual contribution of Th 17 cells in the formation of severe asthma, but also as a promising novel target for a therapeutic intervention. Therefore, the aim of this study is to diminish RORγt expression by using siRNA and to characterize its effects on Th 17 cell activity in-vitro and on neutrophilic asthma in-vivo. **Methods:** We generated OVA-specific Th 17 cells in-vitro, which were transfected with siRNA candidates targeting RORγt. Afterwards, the in-vivo relevance of siRNA-mediated downregulation of RORγt was characterized in a mouse model of neutrophilic asthma. **Results:** We could show that siRNA-transfected Th 17 cells revealed not only a reduced expression of RORγt in-vitro but also of proinflammatory cytokines like IL-17A and IL 17F. Intra-tracheal application of the RORγt-specific siRNA, which was most active in the in-vitro setting, inhibited the development of airway hyperresponsiveness (AHR) to methacholine and decreased bronchoalveolar lavage IL-17A, TNF-α and KC levels. Consequently, application of the RORγt-specific siRNA significantly reduced the number of neutrophils and of lymphocytes. **Conclusion:** These results indicate that targeting RORγt could be a new approach for the treatment of neutrophilic asthma

Disease Area: COPD

6 Acute phase protein α1-Antitrypsin – a novel regulator of angiopoietin-like protein 4 transcription and secretion

Frenzel E[1], Wrenger S[1,3], Immenschuh S[1], Koszulla R[2,4], Welte T[1,3], Janciauskiene S[1,3]
[1]Hannover Medical School, Hannover; [2]Philipps-Universität Marburg, Marburg; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [4]Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376775

The angiopoietin-like protein 4 (angptl4, also known as peroxisome proliferator-activated receptor (PPAR) gamma induced angiopoietin-related protein) is a multifunctional protein associated with acute phase response. The mechanisms accounting for the increase in angptl4 expression are largely unknown. This study is the first to show that human α1-antitrypsin (A1AT) up-regulates expression and release of angplt4 in human blood adherent mononuclear cells and in primary human lung microvascular endothelial cells in a concentration- and time-dependent manner. Mononuclear cells treated for 1 h with A1AT (from 0.1 to 4 mg/ml) increased mRNA of angptl4 from 2 to 174-fold, respectively, relative to controls. In endothelial cells the maximal effect on angptl4 expression was achieved at 8 h with 2 mg/ml of A1AT (11-fold induction versus controls). In ten emphysema patients receiving A1AT therapy (Prolastin) plasma angptl4 levels were higher relative to patients without therapy [ng/ml, mean (95% confidence interval) 127.1 (99.5 – 154.6) versus 76.8 (54.8 – 98.8), respectively, p = 0.045] and correlated with A1AT levels. The effect of A1AT on angptl4 expression was significantly diminished in cells pre-treated with a specific inhibitor of ERK1/2 activation (UO126), irreversible and selective PPARγ antagonist (GW9662), or genistein, a ligand for PPARγ. GW9662 did not alter the ability of A1AT to induce ERK1/2 phosphorylation, suggesting that PPARγ is a critical mediator in the A1AT-driven angptl4 expression. In contrast, the forced accumulation of hypoxia inducible factor 1-α, an up-regulator of angptl4 expression, enhanced the effect of A1AT. Thus, acute phase protein A1AT is a physiological regulator of angptl4, another acute phase protein.

7 Peptide of alpha1-antitrypsin: potential novel therapy

Wrenger S[1,2], Welte T[1,2], Janciauskiene S[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376776

Background: We confirmed that alpha1-antitrypsin (A1AT) exhibits immunomodulatory activities that are unrelated to inhibition of neutrophil elastase. A1AT does not suppress but rather modulates production of pro- and anti-inflammatory substances, dependent on the cell/tissue response magnitude (output) to pro-inflammatory stimuli. A1AT down-regulates a hyper-immunity or hyper-inflammation without impairing the normal immune or inflammatory response necessary to defend against infection or injury. **Methods:** Human blood neutrophil and monocyte isolation by gradient centrifugation, explanted lung tissue culture, A1AT peptide synthesis, gene expression (RT-PCR), western blots, ELISA, cell adhesion, phagocytosis and viability assays, spectrophotometry, flow cytometry. **Results:** We have selected synthetic C-terminal peptide of A1AT, which significantly modulates endotoxin-induced pro-inflammatory cytokine and chemokine release and expression (like IL-8, MCP-1, IL-1β, IL-6 and TNFα), increases neutrophil phagocytic activity and shows no toxic effects on human cell and lung tissue models ex vivo. **Conclusion:** We propose that A1AT-based short peptides that mimic immunomodulatory properties of our own endogenous A1AT are excellent candidates for the drug development. Research Support: Hannnover Medical School, German Center for Lung Research (DZL) **References:** Janciauskiene S and Welte T. 2013 Cardiovascular & Hematological Disorders-Drug Targets

8 The role of surfactant protein D in fibrotic lung remodelling

Viereck J[1], Knudsen L[2,3], Schneider JP[2,3], Ochs M[2,3], Thum T[3]
[1]Institute of Molecular and Translational Therapeutic Strategies, Hannover Medical School, Hannover; [2]Institute of Functional and Applied Anatomy, Hannover Medical School, Hannover; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376777

Objective: Chronic obstructive pulmonary disease (COPD) is a strong risk factor for cardiovascular disease, since even moderate airflow reduction increases the danger of ischemic heart disease, stroke, arrhythmias, heart failure, and sudden cardiac death. COPD is associated with enhanced inflammatory response in the airways and the lung tissue accompanied by a complex remodelling process with fibrosis as one possible outcome. Surfactant protein D (SP-D), a collectin with immunmodulatory function, has been implicated in the pathogenesis of COPD and is seen as a potential biomarker for idiopathic interstitial fibrosis, although its role in this disease remains elusive. In this study we aimed to test the hypothesis that SP-D plays an important role in the fibrotic remodelling by characterizing a mouse model deficient in SP-D. **Methods:** SP-D knockout mice were analyzed at different time points (after 3 and 6 months, 1 and 1.7 years) by design-based stereology and lung function was assessed. We further determined the expression of fibrotic marker genes including microRNAs in lung tissue applying quantitative real-time polymerase chain reaction. **Results:** Compared to wilde-type littermates, SP-D-deficient mice exhibited thicker alveolar septae, predominantly in the interstitium, and this increase was strengthened over time. We further observed a significant elevation of pro-fibrotic microRNAs (miR-21 and miR-155) in lung tissue of SP-D-deficient mice as well as a deregulation of collagen, transforming growth factor β1, and

vimentin. **Conclusion:** These findings indicate that the deficiency in SP-D favours a pro-fibrotic remodelling in the lung altering the morphology of the alveolar interstitium as well as the expression of fibrosis-related genes.

9 Can health-economic modeling be adjusted to assess the cost-effectiveness of prognostic testing in COPD management?

Wacker M[1,2], Holle R[1], Leidl R[1,2]
[1]Helmholtz Zentrum München, Munich; [2]Comprehensive Pneumology Center München (CPC-M), Member of the German Center for Lung Research (DZL), Munich
DOI: 10.1055/s-0034-1376778

Background: Genetic mutations like ADRB2 polymorphisms are suspected to influence treatment outcomes in COPD [1]. Clinical application of pharmacogenetic testing may improve treatment and cost outcomes in COPD. This paper analyzes whether effectiveness and cost-effectiveness of genetic testing for mutations and stratified treatment can be assessed by testing and adapting an existing COPD Markov model. **Methods:** The German COPD model is a comprehensive Markov model (disease stages I-IV according to GOLD, post-surgery, post-LTx, death) and considers mild, moderate and severe exacerbations [2]. It was developed to conduct cost-utility analyses. The model was extensively cross-validated in an international COPD modeling workshop led by Erasmus University Rotterdam. For evaluating stratified approaches, the model needs to be adjusted to compare COPD patients who either receive or do not receive a genetic test before pharmacological treatment. **Results:** Structure and input parameters of the economic CODP model were successfully cross-validated comparing output with several international COPD models. The existing model comprises the entire course of disease, thus it can be adjusted to analyze treatment strategies, and extended for stratified approaches. The model showed good applicability for evaluating cost and effects of different and complex COPD interventions. If novel and experimental markers, e.g. ADRB2 polymorphisms, report sufficient differential impact on treatment while having good sensitivity and specificity, stratified treatment approaches can be meaningfully compared to usual care treatment without genetic testing using this model. Furthermore, information on the prevalence of the mutation in the population as well as on test costs and uncertainty is needed for relevant population-based modeling. **Conclusion:** A German COPD model has been found valid in testing. The model enables adjustments to derive cost-effectiveness estimates of stratified treatment according to prognostic markers in the management of COPD. A consistent reporting of test effects and test characteristics is necessary for reliable cost-effectiveness estimations. **References:** Rabe KF, Fabbri LM, Israel E, et al. Effect of ADRB2 polymorphisms on the efficacy of salmeterol and tiotropium in preventing COPD exacerbations: a prespecified substudy of the POET-COPD trial. Lancet Respir Med. 2014 Jan;2(1):44 – 53. 10 The primary care routine data registry BeoNet: health services and health economic research in COPD and ELD

Lingner H[1,6], Aumann I[2,6], Gottlieb J[1,6], Welte T[1,6], Leidl R[3,7], Vogl M[4,7], der Schulenburg JM von[2,6], Kreuter M[5,8], Wacker M[4,7]
[1]Hannover Medical School, Hannover; [2]Leibniz Universität Hannover, Hannover; [3]Ludwig-Maximilians-Universität München/Helmholtz Zentrum München, München; [4]Helmholtz Zentrum München, München; [5]ThoraxKlinik am UniversitätsKlinikum Heidelberg, Heidelberg; [6]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), [7]Comprehensive Pneumology Center Munich (CPC-M); [8]Translational Lung Research Center Heidelberg, Members of the German Center for Lung Research
DOI: 10.1055/s-0034-1376779

Objectives: Reliable primary care data are needed for health services and health economic research in lung disease like COPD and ELD. Within the German Center for Lung Research, the BeoNet- ("Beobachtungspraxen-Netzwerk") Registry will gather full primary care routine data from electronic patient records for real-time monitoring as well as for longitudinal trans-sectoral cohort studies and combine these data with patient reported outcomes. **Methods:** A real-time, standardized collection of primary care routine data will be established. Basic claims data from electronic patient records of participating general practitioners, pneumologists and pediatricians as well as data on different aspects of care like on diagnosis, treatments and procedures, medication, disease management, treatment frequencies and accounting are accumulated, transferred via standardized interfaces and compiled for analysis. Data on other healthcare utilization, health-related quality of life and further disease-specific parameters will be gathered by additional questionnaires and linked with the electronic health records. **Results:** Important milestones during the pilot phase of the BeoNet-Registry have been achieved so far: (1) project approvals by the ethics committees of Hannover and Munich as well as for the data security concept were obtained; (2) cooperation with software developers was initiated to ensure data extraction and transport; (3) specific questionnaires for additional data were selected, tested and adopted. The ongoing recruitment of the network of surgeries and the construction of the data test-network has been initiated. Until now 51 general physicians agreed to participate, 91 are interested. Physicians engaged in specific health care research projects will recruit target-patients. Over 26.000 patient IDs and the coresponding data entries were transferred as a test dataset from the electronic patient records to the database. First queries are in progress. **Conclusions:** For the improvement of pulmonary healthcare strategies the BeoNet-Registry provides a quality-proved data base for standardized assessments of disease-specific costs, quality of life and for objective outcome evaluation.

11 Alveolar epithelial cells type II show a high sensitivity to cigarette smoke extract

Seehase S[1,3], Baron-Luehr B[1], Kugler C[2], Vollmer E[1], Goldmann T[1,3]
[1]Research Center Borstel, Borstel; [2]LungenClinic Grosshansdorf, Grosshansdorf; [3]Airway Research Center North (ARCN, Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376780

Alveolar epithelial cells type II (AECII) play an important role in the normal pulmonary function as well as in the host defense and immune response. The human tumor cell line A549 is the most popular model of AECII. In the presented study, the effects of cigarette smoke extract (CSE) on primary AECII and A549 as well as the epithelial adenocarcinoma cell line H1975 were investigated. Tumor-free lung tissue from patients who underwent lobectomy due to cancer at the LungenClinic Großhansdorf was used to isolate AECII. Briefly, after crushing the lung tissues, AECII were separated by negative selection via a CD45. Subsequently, cells were seeded on collagen-coated 96-well plates at low density (4×10^4 cells/well). A549 cells were seeded at 2 x 105 cells/well, H1975 at 2×10^4 cells/well. All three cell types were maintained in DMEM-F12 supplemented with 10% FCS overnight. CSE was obtained using commercially available cigarettes (West light) by drawing smoke of one cigarette slowly through a water pump into a tube containing 10 mL of ddH2O (= 10% CSE). Stimulation was performed under serum-free conditions. Cells were stimulated with increasing concentrations of CSE (0.1 – 5%) for 1 h. Cells were cultured for further 4 h. Cell viability was measured via MTT assay. Acute CSE exposure with 0.5% CSE induced a significant cytotoxic effect in AECII (IC50: 0.21% CSE), which was not reversible by dexamethasone (4 mg/mL) or roflumilast (15 μM). In H1975, a concentration of 5% CSE caused a significant reduction of cell viability. By contrast, no cytotoxic effect was detectable in A549 cells. Primary AECII are a model to investigate cigarette smoke induced inflammatory effects, better suited than the widely used tumor cell line A549. Moreover, CSE-induced AECII damage is not reversible by anti-inflammatory treatment.

12 In vitro ciliary development in an epithelial stem equivalent cell line M3E3/C3 derived from the fetal Syrian hamster lung

Emura M[1], Manukjan G[1], Chandler N[2], Neuhoff N von[1], Tauscher M[1], Takahashi Y[3], Hegermann J[1], Ochiai A[4], Schlegelberger B[1]
[1]Hannover Medical School, Hannover; [2]The University of Utah School of Medicine, Utah, USA; [3]Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan; [4]National Cancer Center Hospital East, Chiba, Japan
DOI: 10.1055/s-0034-1376781

Failure in airway regeneration after injury may result in profound consequences like a disease with bronchiolitis obliterans. Re-building of ciliated cells is a good marker for resumed airway activity. We decided to investigate whether M3E3C3,a fetal hamster stem equivalent cell line, is capable of in vitro ciliogenesis. Immunoreactivity and qRT-PCR have revealed that this cell line expresses a stem cell marker Sox2 and another marker, Clara cell secretory protein (CCSP) specific for the stem cells in the bronchiolar region. An embryonic stem cell factor Oct4 was negative. The cells 3D-cultured at the air-liquid interface (ALI) exhibited pseudostratification together with apical cytoplasmic ezrin and growth of long cilia when combined with mesenchymal cells (MC) embedded in an underlying collagen (I) gel, inside which the medium flowed vertically and reciprocally. A transcription factor Foxj1, whose expression critically regulating ciliary development was measured by qRT-PCR, became active early in the 3D culture at ALI and rapidly diminished a few days before the start of the ciliogenesis. The ciliated cells were also detectable by immunoreaction to β-tubulin IV antibody or optical recognition of ciliary beating. They can grow when the ALI conditions are met even without the co-presence of MC, but the morphology of the cilia is often dwarfed, as observed by electron microscopy. However, on a Matrigel film even under ALI conditions alone the cilia appear to develop normally. Fibrillar collagen (I) and Matrigel, instead of the living MC could not support pseudostratification in the epithelium, although beating cilia were induced despite their size or form. The results show that the airway stem equivalent cell line can be coaxed in vitro into forming a pseudostratified epithelial architecture and cilia in the adequate microenvironment. This stem equivalent cell line may thus constitute a useful experimental system for exploring the mechanisms of airway epithelium regeneration.

13 Immunoaging augments sensitivity to cigarette smoke-induced COPD

Günter S[1], John-Schuster G[1], Conlon T[1], Hager K[1], Eickelberg O[1], Önder Yildirim A[1,]*
[1]Comprehensive Pneumology Center, Institute of Lung Biology and Disease, Helmholtz Zentrum München, Member of the German Center for Lung Research (DZL), Munich
DOI: 10.1055/s-0034-1376782

The pathogenesis of COPD is related to an abnormal inflammatory response of the lungs to cigarette smoke, toxic gases and particles, which leads to emphysema, chronic bronchitis and subsequent decline in lung function. Age-related changes of immune system functions have been described, but are complex phenomena incompletely understood. We hypothesize that in a chronic CS-induced mouse model the pathogenesis of COPD is characterized by an elevated immune response in aged mice. 2 and 12 months old C57BL/6 mice were exposed to CS concentration of 500 mg/m3 TPM for 3 months. BAL fluid was sampled to perform differential cell counts and inflammatory cell recruitment in lung tissue was measured by FACS. Lung function and emphysema development were also determined. Only in aged mice an increase in lung compliance was noticeable after 3 months of CS exposure compared to control and young animals. Emphysema development in CS-exposed aged mice compared to younger animals substantiated these findings. A significantly greater volume of iBALT structures in aged mice after CS exposure was shown by quantification of lung tissue inflammation. Staining for MMP12 in lung tissue indicated significantly higher macrophage accumulation and activation in CS-exposed aged mice, which was in accordance with increased MMP12 expression and an elevated MMP12/TIMP1 ratio. Differential cell counts of BAL cytospins revealed significantly higher lymphocytes only in CS-exposed aged animals. Interestingly, an increase in Th17 cells in the lung could only be shown in CS-exposed aged mice compared to control animals. These results strongly suggest that lung inflammation after CS exposure is augmented in aged mice, which might be related to an age-induced change in gene expression profiles. This suggests a role for age-related inflammatory changes in the pathogenesis of COPD.

14 Evaluation of small molecule FRET reporter for the diagnosis and monitoring of proteolytic activity in a chronic obstructive lung disease model

Reither G[1,3], Heath N[2,3], Holz O[4], Kahn N[3,5], Hohlfeld J[4], Schultz C[2,3], Mall MA[1,3]
[1]Department of Translational Pulmonology, University of Heidelberg, Heidelberg, Germany; [2]European Molecular Biology Laboratory, Heidelberg; [3]Translational Lung Research Center (TLRC); [4]Fraunhofer ITEM Hannover (BREATH), Member of the German Center for Lung Research (DZL); [5]Departments of Pneumology and Critical Care Medicine, Thoraxklinik, University of Heidelberg, Heidelberg
DOI: 10.1055/s-0034-1376783

Proteases such as neutrophil elastase (NE) and matrix metalloprotease 12 (MMP-12) are key factors in inflammatory processes and contribute the gradual destruction of extracellular lung matrix in chronic inflammation. We now hypothesize that activity levels of inflammation-relevant proteases may be useful indicators for the onset and progression of obstructive lung diseases such as cystic fibrosis or COPD. With the recently published small molecule FRET protease reporters NEmo and LaRee, for detection of NE and MMP-12 activity, respectively, it is possible to monitor protease activity at the single cell level. The goal of this study is to apply protease activity measurements to sputum specimens from patients with chronic obstructive lung diseases. We investigated the impact of sample generation and experimental conditions on the performance and outcome of diagnostic protease monitoring in sputum samples in general. We tested the new approach on a double blinded sample set from the Fraunhofer ITEM Hannover (BREATH). In this study healthy subjects were exposed to irritating conditions or control air in an incubation room. Sputum was produced and processed by standard operation procedure. Through comparison of by-hand analysis, we succeeded in receiving satisfactory data sets via automated cell analysis of hundreds of cells per sample using novel macros. This assay format is now expanded to employ additional small molecule protease probes for cathepsin B and S. Our novel approach of the assessment of protease activity at the single cell level applied to multiple protease types may result in a new tool for diagnosis and monitoring. The detection of patient specific protease activity patterns may improve the differentiated diagnosis and therapeutic strategies.

Disease Area: Cystic Fibrosis

15 Functional analysis of regulatory variants that determine the outcome of the monogenic disease cystic fibrosis

Awah C[1,2], Tamm S[1], Hedtfeld S[1], Tümmler B[1,2], Stanke F[1,2]
[1]Hannover Medical School, Paediatrics Institute, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376784

The clinical outcome of patients with Cystic Fibrosis is highly variable, even among patients who harbour the same CFTR mutation genotype, indicating that environmental and non-CFTR genetic factors such as modifying genes shape the course of the disease. Two contrasting alleles (C or T) of SNP rs7910656 on intron 2 of the FAS gene have been associated with mild and severe CF outcome. To gain mechanistic insight into how the SNPs of FAS alter the course and the outcome of the disease, we performed in- silico analysis using ENCODE data which showed that rs7910656 is on a nucleosome free region and occupied with RNA POLII and H3k36me3. We have also identified a novel secondary promoter start site which is +4.5kb from rs7910656. Analysis into differential transcription factor occupancy of rs7910656 and controls rs2147420, rs1571019 showed that 29 TFs, mostly of immune regulating family occupied rs7910656 while 6 and 7TFs are on rs2147420and rs1571019 respectively. We also have found that the C-allele of rs7910656 is bound by 6 TFs (NFKB, STAT4, HIF1A, MAFA, NURR1 and TEAD) which are not observed for the T-allele. More so, the C-allele makes multimeric complexes with NFKB (p65, p50, C-Rel), binds with three motifs to STAT4 and binds with one motif to HIF1A, while T-allele does not bind with

NFKB and HIF1A but binds with two motifs to STAT4. We have designed probes for the TFs and have developed a nuclear extraction protocol that preserves the transcription factors in their native states (phosporylated and acetylated) and have carried out an Electrophoretic Mobility Shift Assay with biotinylated probes of p65 subunit of NFKB,C and T-allele of rs7910656. We found the robust binding of p65 subunit and have shown that C-allele binds more robustly than T-allele, which is consistent with our in-silico predictions.

16 Silencing of miR-148b ameliorates cystic fibrosis-like lung diseases in βENaC-overexpressing mice

Agrawal R[1], Castoldi M[2], Altamura S[2], Stanke F[3,5], Meister M[3], Muley T[3,5], Greene CM[4], Tümmler B[3,5], Muckenthaler MU[2], Mall MA[1,5]

DOI: 10.1055/s-0034-1376785

MicroRNAs are involved in diverse biological and pathological processes. Here, we studied the potential role of miRNAs in the in vivo pathogenesis of cystic fibrosis (CF)-like lung disease in βENaC-overexpressing (βENaC-Tg) mice. We performed miRNA array analysis in lung tissue of βENaC-Tg and wild-type mice. Differentially expressed miRNAs were validated by qRT-PCR and their target genes were identified by bioinformatics analysis and luciferase reporter assays. Tissue specific localization was performed by in situ hybridization using locked nucleic acid-modified DNA probe. Direct functional studies were performed by knockdown of miRNA expression in the lungs of βENaC-Tg mice using antagomirs. The effects of knockdown were studied by lung histology, analysis of inflammatory cells in bronchoalveolar lavage and pulmonary function testing using flexiVent system. Genetic association studies in CF patients were performed by analyzing miR148b-Sat1 allele frequency. We demonstrate that miR-148b is upregulated in the lungs of βENaC-Tg mice and predominantly localized in conducting airway and alveolar epithelial cells. Luciferase reporter assay in Hela cells suggests Mig-6 (mitogen inducible gene-6), a protein previously shown in normal lung development, as a potential target of miR-148b. Antagomir-mediated knockdown of miR-148b in the lung of βENaC-Tg mice reduced emphysema formation, goblet cell metaplasia and neutrophillic inflammation. Further, we observed upregulation of miR-148b in human cystic fibrosis and COPD lung tissue, as well as its localization in airway and alveolar epithelial cells. Finally, our genetic association studies establish that distribution of miR148b-Sat1 allele, closely linked to the MIR148b genomic locus in human, is associated with disease manifestation among F508del-CFTR homozygous sibling pairs. Collectively, these results indicate that deregulation of miR-148b may play an important role in the pathogenesis of CF and COPD and may serve as a novel therapeutic target.

17 ICM is sensitive to detect potentiation of CFTR-mediated Cl- secretion in patients with cystic fibrosis and the G551D mutation treated with ivacaftor

Graeber SY[1,2,8], Hug MJ[3], Sommerburg O[1], Mainz JG[4], Hentschel J[4], Heinzmann A[5], Tuemmler B[6,7], Mall MA[1,2,8]
[1]Division of Pediatric Pulmonology & Allergy and Cystic Fibrosis Center, Department of Pediatrics, University of Heidelberg, Heidelberg; [2]Department of Translational Pulmonology, University of Heidelberg, Heidelberg; [3]Pharmacy, University Medical Center Freiburg, Freiburg; [4]Department of Paediatrics, Jena University Hospital, Jena; [5]Centre for Pediatrics and Adolescent Medicine, University of Freiburg, Freiburg; [6]Department of Pediatrics, Hannover Medical School, Hannover; [7]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [8]Translational Lung Research Center Heidelberg (TLRC), Members of the German Center for Lung Research
DOI: 10.1055/s-0034-1376786

Background: Sensitive outcome measures of CFTR function may facilitate the implementation of mutation-specific therapy with CFTR modulators in patients with cystic fibrosis with non-G551D mutations. Intestinal current measurement (ICM) is a sensitive assay for functional assessment of mutant CFTR in rectal biopsies and was recently shown to detect potentiator effects of 1-EBIO ex vivo (Roth E. et al., PLOS ONE 2011). The aim of this study was to determine, if ICM is sensitive to detect potentiation of CFTR-mediated Cl^- secretion in rectal epithelia from CF patients with a G551D mutation treated with ivacaftor. **Methods:** Rectal biopsies were obtained from 8 patients carrying a G551D-CFTR mutation before and at least four weeks after the start of ivacaftor therapy. Rectal tissues were mounted in micro-Ussing chambers and CFTR-mediated Cl^- secretion was determined from Cl- secretory responses induced by cAMP (IBMX/forskolin)- and Ca^{2+} (charbachol)-mediated stimulation. **Results:** Before ivacaftor therapy, ICM detected variable residual CFTR-mediated Cl- secretion in rectal tissues from CF patients with a G551D mutation. In the presence of ivacaftor therapy, CFTR-mediated Cl^- secretory responses were increased in all 8 patients. **Conclusion:** We conclude that ICM is sensitive to detect in vivo potentiation of mutant CFTR function by treatment with ivacaftor. Our results indicate that ICM may be a useful bioassay to determine therapeutic responses at the level of the basic CF defect of ivacaftor and potentially other clinical CFTR modulators in CF patients with non-G551D mutations.

18 Rescue of function in a cystic fibrosis mouse model by transfer of hematopoetic stem cells

Munder A[1], Struß R[2], Schambach A[2], Tümmler B[1,3]
[1]Clinic for Pediatric Pneumology, Allergology and Neonatology, Hannover Medical School, Hannover; [2]Department of Experimental Hematology, Hannover Medical School, Hannover; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376787

Cystic fibrosis (CF) is the most common hereditary disease in the Caucasian population. The disease causing gene CFTR was identified in 1989. So far, more than 1,800 mutations have been identified in the *CFTR* gene [1], which codes for a cyclic adenosine monophosphate-regulated chloride channel. The malfunction of this channel leads to a progressive loss of function in the CF lung, which is the decisive factor for morbidity and mortality of most CF patients. Beside mucus accumulation in the airways, also an impaired phagocytosis in alveolar macrophages seems to play an important role in the pathogenesis of chronic infection and inflammation in the CF lung [2]. The Gram-negative, ubiquitous opportunistic pathogen *Pseudomonas aeruginosa* is the key organism in causing CF lung disease. CF mouse models are an extremely suitable tool to investigate *Pseudomonas* lung pathogenicity. In our study presented here, we tested whether the increased genetic susceptibility of CF mice to airway infection with *P. aeruginosa* can be reduced to levels of wild-type mice by transfusion of hematopoietic stem and precursor cells (HPSPCs) of *Cftr* wildtype mice. Therefore, we subjected recipient *B6.Cftr*$^{TgH(neoim)Hgu}$ mice to a lethal dose of irradiation and injected them with hematopoietic progenitor cells from B6 wildtype donor mice. After a six weeks phase of reconstitution mice were infected intratracheally

with a disease causing dose of the cytopathic *P. aeruginosa* strain PAO1. The course of infection was monitored over 144 h measuring murine lung function, body weight, rectal temperature and survival of the mice. *B6.Cftr$^{TgH(neoim)Hgu}$* mice which received isogenic HPSPCs served as controls. **References:** [1] Cystic Fibrosis Mutation Database (2014) http://www.genet.sickkids.on.ca/cftr/app Accessed 12 March 2014 [2] Di A, Brown ME, Deriy L V, Li C, Szeto FL 1, Chen Y, Huang P, Tong J, Naren AP, Bindokas V, Palfrey HC and Nelson DJ. 19 The effector protein ExoY secreted by Pseudomonas aeruginosa augments the inflammatory reaction in the respiratory tract of mice

Munder A[1], Hartwig C[1], Schirmer B[1], Stelzer T[1], Tümmler B[1,3], Seifert R[1]
[1]Clinic for Pediatric Pneumology, Allergology and Neonatology, Hannover Medical School, Hannover; [2]Institute of Pharmacology, Hannover Medical School, Hannover; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376788

Infection with the gram-negative opportunistic pathogen *P. aeruginosa* causes serious pulmonary, urogenital and systemic inflammation in immunodeficient patients. Most prominently, *P. aeruginosa* is the key organism responsible for pneumonia in cystic fibrosis patients, defining the course of the disease as well as its prognosis. *P. aeruginosa* produces a wide variety of effector proteins and injects them into host cells via the type III secretion system [1]. One of the effectors, injected by this needle-like structure is ExoY, which can be found in 90% of clinical isolates from *P. aeruginosa*. Despite of the highly frequent ExoY occurrence, its function is still unknown. While previous publications described ExoY to be apathogenic, our recent in vivo studies demonstrated a distinct role of ExoY as a pathogenic factor of *P. aeruginosa*. In our murine infection model we infected B6 mice intratracheally with $1 \times 10^{6-8}$ colony forming units (cfu) of two *P. aeruginosa* strains, the first expressing a functional ExoY, the second the catalytically inactive ExoY mutant K81 M [2]. Mice were sacrificed 0 – 48 h after infection and bacterial infection was characterized by analyzing the migration of neutrophils into the lung and inflammatory cytokines in the respiratory tract. Infection doses of 10^7 cfu/mouse lead to ExoY-dependent, severe pathological changes in lung tissue and to increased mortality. Even more distinct effects were seen at concentrations of 10^8 cfu/mouse. Within 4 to 8 hours severe signs of infection and lung inflammation were observed. Lethality occured 24 – 48 hours after infection. Inflammatory lung reaction was characterized by interstitial edema, hemorrhagic infiltration and necrotic/apoptotic areas in the tissue. Secretion of proinflammatory factors such as IL-6, IL-1, MCP-1 and KC was significantly increased in the ExoY infected groups. **References:** [1] Hauser AR. The type III secretion system of Pseudomonas aeruginosa: infection by injection. Nat Rev Microbiol 2009 7: 654 – 665 [2] Yahr TL, Vallis AJ, Hancock MK, Barbieri JT and Frank DW. 20 Population biology of Pseudomonas aeruginosa in chronic CF and COPD airway infections

Wiehlmann L[1,4], Cramer N[1], Sikorski J[2], Klockgether J[1], Davenport C[1], Winstanley C[3], Tümmler B[1,4]
[1]Hannover Medical School, Hannover; [2]DSMZ, Braunschweig; [3]University of Liverpool, Liverpool; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376789

To analyse the population structure of Pseudomonas aeruginosa, more than 1400 independent isolates from diverse environmental and clinical habitats and geographic origins were investigated by SNP- typing of core genome and markers of the accessory genome. More than 50% of all isolates belonged to less than 25 dominant clones widespread in disease and environmental habitats. Moreover, most clones group in only a few clonal complexes. These complexes seem to be phylogenetically ancient and related to specific sets of genomic islands, e.g. exoU islands. This implies that recombinations between strains of different complexes are rare events. While most clones were found in the environment, only a subgroup of these strains has been found to date in humans. Moreover, beside some extremely frequent generalists, most strains were related to a specific mode of infection or habitat. For example, the clones dominating in cystic fibrosis (CF) are also dominant in chronic obstructive pulmonary disease (COPD), acute lung infections and urinary tract infections. To investigate the microevolution of P. aeruginosa in the human lung, serial CF airway isolates of the globally most frequent clones C and PA14 were collected over 20 years since the onset of colonization. The intraclonal evolution in CF lungs was resolved by genome sequencing of first, intermediate and late isolates and subsequent multimarker SNP genotyping of the whole strain panel. While the PA14 clone diversified into three branches in the patient's lungs and acquired 15 nucleotide substitutions and a large deletion during the observation period, the clone C genome remained invariant during the first years in CF lungs; however, 15 years later 947 transitions and 12 transversions were detected in a mutL mutant strain. Late persistors in CF lung habitats were compromised in growth and cytotoxicity, but their mutation frequency was normal even in mutL mutant clades.

21 Strategies to identify clinically relevant interaction partners of cystic fibrosis modifying genes: analysis of SCNN1B

Stanke F[1]
[1]Department of Pediatrics, Hannover Medical School, Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376790

The course of the monogenic disease cystic fibrosis is influenced by non-genetic factors and by CF modifier genes. During the last years, several CF modifying genes were identified and the clinically relevant variants were mapped by the base in the patient population of the European CF Twin and Sibling study. The identified genetic variants largely are located within the non-coding sequence of the human genome, thus implying that they do not change the amino acid sequence of the corresponding modifier gene but instead reflect an essential regulatory mechanism. During the last years, we have used complementary technologies to describe the molecular mechanism that governs the expression of the cystic fibrosis modifier gene SCNN1B. To identify the causative variants, 3 microsatellites and 45 SNPs were genotyped on 101 families with a total of 171 F508del-CFTR homozygous CF patients. Resequencing of two 8000 bp fragments for which discordant and concordant sibling pairs carry contrasting genetic information has revealed six possible causative SNPs. Bioinformatic predictions and subsequent testing of the predicted interaction partners as candidate genes have so far confirmed one transcription factor as a CF modifying gene. Using both alleles of the six identified SCNN1B SNPs in a comparative electrophoretic mobility shift assay and subsequent protein sequencing of the excised bands has revealed previously unknown novel DNA-protein interactions that are likely to mediate SCNN1B expression. Continuous support by the Fritz-Thyssen-Stiftung is gratefully acknowledged.

22 Imaging cilial motion by endoscopic optical coherence microscopy

Schulz-Hildebrandt H[1], Pieper M[2], König P[2], Hüttmann G[1,3]
[1]Institute of Biomedical Optics, University of Lübeck, Lübeck; [2]Institute of Anatomy, University of Lübeck, Lübeck; [3]Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376791

Endoscopic imaging gives minimally invasive access to the airways and can provide important diagnostic information. We have shown that optical coherence microscopy (OCM), the combination of confocal microscopy and optical coherence tomography is able to image airway tissue with subcellular resolution. Due to its high imaging speed and lack of tissue damage OCM is a promising technique for clinical imaging if it can be integrated into endoscopic imaging devices. Here, we present endoscopic OCM imaging of airway tissue using a rigid GRIN lens based endoscopes. Beating motion of cilia and particle transport was visualized with up to 50 Hz temporal resolution. Presently,the probe can be used for small animal imaging. Work is under progress to convert the

rigid endoscopy into flexible probe which can be used for human imaging

23 Downregulation of Hemeoxygenase-1 and Altered Cellular Homeostasis in Cystic Fibrosis

Chillappagari SP[1], Venkatesan S[2], Garapati V[1], Mahavadi P[2], Munder A[3], Seubert A[1], Guenther A[2,5], Schmeck B[1,5], Tümmler B[3,4], Henke M[1]
[1]Philipps University Marburg, Marburg; [2]Justus-Liebig-Universität Gießen, Gießen; [3]Hannover Medical School, Hannover; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [5]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376792

Hemeoxygenase-1 (HO-1), an inducible heat shock protein, is upregulated in response to multiple cellular insults via oxidative stress, lipopolysaccharides (LPS), and hypoxia. In this study, we investigated the role of toll-like receptor 4 (TLR4), hypoxia-inducible factor-1α (HIF-1α) and iron on HO-1 expression in cystic fibrosis (CF). Immunohistochemical analysis of TLR4, HO-1, ferritin and HIF-1α were performed on lung sections of CFTR-/- and wildtype mice. CFBE41o- and 16HBE14o- cell lines were employed for in vitro analysis via immunoblotting, immunofluorescence, real-time PCR, luciferase reporter gene analysis and iron quantification. We observed a reduced TLR4, HIF-1α, HO-1, and ferritin in CFBE41o- cell line and CF mice. Knockdown studies using TLR4-siRNA in 16HBE14o- revealed significant decrease of HO-1, confirming the role of TLR4 in HO-1 downregulation. Inhibition of HO-1 using tin protoporphyrin in 16HBE14o- cells resulted in increased iron levels suggesting a probable role of HO-1 in iron accumulation. Additionally, sequestration of excess iron using iron chelators resulted in increased HRE response in CFBE41o- and 16HBE14o- implicating a role of iron in HIF-1α stabilization and HO-1. To conclude, our results demonstrate that downregulation of HO-1 expression in CF is resulted due to reduced TLR4 expression and increased intracellular iron and decreased HIF-1α.

Disease Area: Acute Lung Injury

24 Influenza virus impairs fibroblast growth factor receptor 2b dependent epithelial regeneration from a distal airway epithelial progenitor pool

Quantius J[1], Schmoldt C[1], Hoegner K[1], El Agha E[1], Seeger W[1,2], Lohmeyer J[1,2], Bellusci S[1,2], Herold S[1,2]
[1]University of Gießen Lung Center, Gießen; [2]University of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376793

IV (influenza virus) pneumonia is associated with apoptotic damage of the alveolar epithelial barrier and therefore efficient alveolar repair is crucial for recovery. Lineage tracing studies suggest that the adult lung contains epithelial progenitor cells which proliferate after injury. Fibroblast growth factor 10 (FGF10) plays a major role in lung development and is also known to have reparative, anti-apoptotic potential after injury. We therefore investigated if FGF10 would support alveolar epithelial repair processes after IV-induced pneumonia. Following IV infection or naphthalene treatment, epithelial progenitor cells (EpProg), defined as EpCamhighCD 49fhighCD 104+ Sca-1int showed increased resistance to apoptosis and revealed high proliferation rates. This response was likely mediated by upregulation of the FGF10 receptor FGFR2b on EpProg post IV infection or naphthalene treatment. However, EpProg were found to be primary targets of IV infection, which resulted in reduced FGFR2b upregulation and renewal capacity in the infected compared to the non-infected fraction of EpProg, likely due to virus-induced blockade of the wnt signaling pathway mediating FGFR2b upregulation. Notably, the extent of EpProg infection correlated with the pathogenicity of different IV strains, suggesting that the severity of viral pneumonia might be associated with impairment of FGF10/FGFR2b-mediated epithelial cell renewal. Intratracheal application of recombinant or overexpression of FGF10 increased the reparative response of EpProg, whereas dominant negative FGFR2b overexpression resulted in reduced proliferation rates, sustained alveolar leakage and poor outcome. We provide evidence that IV-induced blockade of the FGF10/FGFR2b axis may result in reduced epithelial cell renewal capacity and poor outcome and that induction of an FGFR2b-dependent pathway may represent a therapeutic approach to overcome IV-induced impairment of epithelial renewal and to drive tissue repair after injury.

25 Therapeutic potential of murine bone marrow derived mesenchymal stem cells in influenza virus-induced pneumonia

Jankauskaite L[1], Schmoldt C[1], Lohmeyer J[1,2], Herold S[1,2]
[1]Department of Internal Medicine, Justus-Liebig-University, Gießen; [2]University of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376794

Influenza virus (IV) infects the human upper respiratory tract and occasionally spreads to the alveolar compartment causing primary pneumonia. This can lead to acute respiratory distress syndrome (ARDS) with severe alveolar damage, lung oedema and hypoxemia. Antiviral therapies are only effective in the very beginning of infection and specific treatment strategies for IV-induced ARDS are lacking. Recent studies have shown the anti-inflammatory and regenerative potential of mesenchymal stem cells (MSC). MSC display a beneficial role in acute and chronic lung injury, suggesting that MSC delivery may be a promising treatment strategy in IV-induced ARDS [1]. We isolated MSC cells from the bone marrow of 8 to 12 weeks old C57Bl6 mice by cell sorting [2]. We characterised their expression markers by flow cytometry and we confirmed their differentiation potential into chondrocytes, osteocytes and adipocytes by microscopy. We co-cultured primary murine alveolar epithelial cells (AECs) with sorted MSC. During influenza infection with PR8 strain, the presence of MSC drastically reduced apoptosis and infection level in AECs. We tested the effect of MSC intratracheal instillation in PR8-infected mice. Similarly to the in vitro experiments, the addition of MSC improved clinical outcomes in comparison with PBS-instilled control mice. Our experiments show the beneficial role of MSC in PR8-induced injury in vitro and in vivo. Taken together our results support that MSC can be of great value to treat IV-induced lung injury. **References:** Gupta N. et al. 2007.Intrapulmonary delivery of bone marrow-derived mesenchymal stem cells improves survival and attenuates endotoxin-induced acute lung injury in mice. J. Immunol,179(3):1855 – 1863. Houlihan D.D. et al. 2012. Isolation of mouse mesenchymal stem cells on the basis of expression of Sca-1 and PDGFR-α. Nat protoc,7(12):2103 – 11.

26 Therapeutic effects of fibroblast grow factor 10 (FGF 10) after hyperoxic lung injury in mice

Chao CM[1], Al Alam D[2], Schermuly R[1,4], Ehrhardt H[3], Zimmer KP[3], Bellusci S[1,4]
[1]Excellence Cluster Cardio-Pulmonary System, University of Gießen, Gießen; [2]Saban Research Institute, Los Angeles, USA; [3]University Childrens Hospital, Gießen; [4]University of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376795

Background and aims: Bronchopulmonary dysplasia (BPD), a chronic lung disease of preterm infants, is characterized by impaired alveolar growth and pathologic vascularization. This project aims to investigate the role of Fibroblast growth factor 10 (Fgf10) in hyperoxic lung injury. **Methods:** 10 weeks old Fgf10+/- mice (50% Fgf10 expression compared to WT) in normoxic condition: Lung function and morphometric analysis. BPD model: Fgf10+/- and Fgf10+/+ mice were exposed to 85% O2 from P0-P8. Morphometric analysis and α-Actin/vWF staining for vessels were performed at P3. Rosa26rtTA/+;tet(O)Fgf10 (gain-of-function) mice were exposed to 85% O2 from P0-P8. From P9-P45 the pups were exposed to normoxia and fed either with normal food (control) or doxycycline food (experimental) to activate the transgene Fgf10. Morphometric analysis was carried out at P45. Tolerance study: Rosa26rtTA/+;tet(O)Fgf10 and WT mice (both 10 weeks old) were exposed to doxycycline for 2 weeks. Then survival rate, histology, Ki67 and TUNEL staining were performed. **Results:** Fgf10+/- mice under normoxic condition have worse lung function and lung structure compared to WT mice. All Fgf10+/- newborn mice die from hyperoxic injury due to increased lung injury and vascular malformation. Overexpression of Fgf10 after hyperoxic injury leads to improvement of lung structure compared to control group without overexpression. Fgf10 overexpression after hyperoxic injury does not increase mortality and side effects (weight loss, mucosal proliferation) are reversible. **Conclusions:** Fgf10 attenuates hy-

peroxic lung injury, is well tolerated and should be further studied as a potential therapeutic for BPD.

27 Role of arginase 1 in lung protective immunity against Streptococcus pneumoniae in mice

Knippenberg S[1,2], Brumshagen C[1,2], Aschenbrenner F[1,2], Welte T[1,2], Maus UA[1,2]
[1]Medical School Hannover, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376796

Type 2 helper cell (TH2) dominated chronic lung diseases like asthma are associated with an increased risk for bacterial lung infections. However, the underlying mechanisms are poorly defined. Arginase 1 has been suggested to play an important role in the pathophysiology of asthma, and is rapidly induced in lung macrophages by TH2 cytokines, thereby limiting macrophage-derived antimicrobial nitric oxide (NO) production. However, the interplay between TH2 cytokine-dependent upregulation of Arg1 and its effect on lung protective immunity against bacterial infection has not been examined in detail. We here examined the effect of TH2 cytokine-induced upregulation or conditional knock-down of Arg1 in macrophages on lung resistance against Streptococcus pneumoniae. Lung macrophages responded with a profound and specific induction of Arg1 mRNA and protein to treatment with TH2 cytokines both in vivo and in vitro. Increased Arg1 activity was accompanied by both significantly attenuated lung protective immunity in mice challenged with S. pneumoniae and attenuated macrophage killing of S. pneumoniae in vitro. In contrast, conditional knock-down of Arg1 in lung macrophages did not impair lung protective immunity against S. pneumoniae, relative to S. pneumoniae-infected WT mice. Collectively, the data show that TH2 cytokine dependent increased but not decreased Arg1 activity worsens lung protective immunity against major lung-tropic pathogens such as S. pneumoniae. Interventions to limit Arg1 activity in the lung might be a novel immunomodulatory strategy for asthmatic patients to cope with bacterial lung infections.

DOI: 10.1055/s-0034-1376797

Introduction: Histone deacetylases (HDACs) are enzymes that remove acetyl groups from an ε-N-acetyl lysine amino acid on histones, resulting in epigenetic repression of gene transcription. HDACs can also catalyze deacetylation of many non-histone proteins, such as the tumor suppressor p53, resulting in inhibition of its pro-apoptotic activity. HDACs thus pivotally control gene expression and cellular signaling. Due to their anti-apoptotic activity, HDACs are upregulated in many cancers. Here, we describe for the first time a biochemical characterization of Class-I/-II/-III-HDACs in lungs from patients with sporadic IPF (n = 16) and organ donors (n = 26). **Methods:** Lung tissue was analyzed by RT-PCR, immunoblotting and immunohistochemistry (IHC). **Results:** Compared to donors, protein-levels of Class-I- (HDAC 1, 2, 3 and 8) and Class-II-HDACs (HDAC 4, 5, 7, 9, 10), and of the Class-III-HDAC Sirtuin-1 were significantly elevated in IPF lungs. By means of IHC, strong nuclear induction of HDACs 1 – 3 and Sirtuin-1 was observed in myofibroblasts of fibroblast foci (FF) and in abnormal bronchiolar basal cells at sites of aberrant re-epithelialization in IPF lungs, but not in donors. Similarly, induced cytoplasmic expression of Class-II-HDACs: 4, 5, 7, 9, 10 and of the Class-III-HDAC Sirtuin-2 could be encountered in FF and basal cells in IPF. Importantly, type-II alveolar epithelial cells (AECII) of IPF-lungs did not reveal notable expression of Class-I/-II/-III-HDACs, possibly due to severe ER stress in this cell type. But IPF-AECII indicated induced cytoplasmic expression of HDAC 6 – a Class-IIb-HDAC involved in aggresome formation. **Conclusions:** We suggest that fibroblast proliferation, fibroblast-to-myofibroblast differentiation and the apoptosis-resistant phenotype of fibroblasts and myofibroblasts in IPF may be mediated due to enhanced expression and action of Class-I/-II/-III-HDACs. Similarly, aberrant overexpression of HDACs in basal cells of IPF lungs may cause the exaggerated, proliferative character of this cell type in IPF and thus govern the process of bronchiolization in this disease. We conclude that HDACs may be novel molecular targets for IPF therapy.

29 Inhibition of profibrotic signaling in fibroblasts from patients with idiopathic pulmonary fibrosis by histone deacetylase-inhibitors or pirfenidone

Korfei M[1], Skwarna S[1], Henneke I[1], Klymenko O[1], Dahlem G[1], Ziegler S[1], der Beck D von[1], Klepetko W[2,7], Fink L[3,7], Seeger W[4,7], Krämer O[5], Guenther A[6,7]

DOI: 10.1055/s-0034-1376798

Introduction: Idiopathic pulmonary fibrosis (IPF) is a fatal disease characterized by distorted pulmonary structure and the excessive deposition of extracellular matrix (ECM) proteins, such as collagen. Myofibroblasts are the primary collagen-producing cells in IPF lungs, and their accumulation within pathologic lesions called fibroblast foci (FF) is a hallmark of IPF. To explore new drugs for IPF, we investigated the therapeutic potential of histone deacetylase inhibitors (HDACi), because we have discovered a significant overexpression of Class-I/-II/-III HDAC enzymes in IPF fibroblasts/myofibroblasts. **Methods:** Primary IPF fibroblasts were incubated for 30 h with the HDACi panobinostat (LBH589, 85nmol) or valproic acid (VPA, 1.5mM), or with the IPF drug pirfenidone (2.7mM). **Results:** Treatment of primary IPF fibroblasts with the pan-HDACi panobinostat resulted in significantly reduced expression of genes associated with fibrogenesis (ACTA2, COL1A1, COL3A1, FN), cell survival (BIRC5 = survivin), proliferation (CCND1), as well as in suppression of HDAC7, and was paralleled by induction of severe ER stress (ATF6, CHOP) and apoptosis (p21, PUMA, cleaved caspase-3). Blockade of Class-I-HDACs by VPA was also associated with reduced expression of BIRC5, but profibrotic gene expression was not greatly altered. Finally, the direct comparison panobinostat – versus pirfenidone therapy showed also for pirfenidone treated IPF fibroblasts a significant downregulation of COL1A1, COL3A1, and FN, but not of CCND1. Furthermore, the profibrotic genes CNN1 and P4HTM were exclusively reduced by pirfenidone -, but not by panobinostat treatment. Importantly, pirfenidone treatment lead also to a significant downregulation of the cancer-associated gene BIRC5, but was not associated with induction of ER stress and pro-apoptotic signaling. Finally, pirfenidone did not greatly affect expression of HDAC proteins. **Conclusions:** We conclude that generation and apoptosis resistance of IPF fibroblasts/myofibroblasts are mediated due to enhanced activity of HDAC proteins, and that panobinostat can present a novel therapeutic option (in addition to pirfenidone) for progressive fibrotic lung diseases.

30 Regulation of autophagy in pulmonary fibrosis

Mahavadi P[1,4], Chillappagari SP[2], Ahuja S[1], Henneke I[1], Klepettko W[3,4], Seeger W[1,4], Guenther A[1,4]

DOI: 10.1055/s-0034-1376799

Importance of lysosome related pathways under conditions of idiopathic pulmonary fibrosis is not extensively studied till date. Autophagy has been known from several years as a self-eating catabolic pathway, activated mainly to degrade the cell's own unused organelles, macromolecules and long-lived proteins via the lysosomal system. Here, we aimed to study the regulation of autophagy in idiopathic pulmonary fibrosis as well as in murine model of bleomycin induced lung fibrosis. Markers of different forms of autophagy were analyzed in the lungs of IPF patients, healthy donors and vehicle or bleomycin treated mice. Levels of p62, LC3BI or LC3BII or their ratios did not vary between IPF and healthy donor lungs. Immunohistochemistry on lung sections revealed an intense staining for autophagy proteins in AECII as well as in fibroblasts of IPF lungs as compared to donor lungs. An increase in the levels of transcription factor EB (TFEB), and its nuclear localization was observed in AECII of IPF lungs. Chaperone-mediated autophagy (CMA) levels decreased in IPF lungs, as denoted by the levels of lysosome-associated membrane protein 2a (LAMP2a). On the contrary, bleomycin injured mouse lungs showed an increase in the autophagy markers, LC3BII, p62, Atg7 and Atg12. Levels of TFEB protein was also increased in bleomycin treated mice lungs. An overall increase in CMA was observed. We conclude that different autophagy pathways are differentially regulated in IPF and in bleomycin injured mouse lungs.

31 Interplay of FGF and Wnt signaling in regulating mesenchymal progenitor cell lineages formation during lung development and repair after injury

Bellusci S[1,2]
[1]Excellence Cluster Cardio-Pulmonary System, Gießen; [2]University of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376800

Over the years our research group has focused on the formation of the different mesenchymal cell lineages during lung development and their respective function during repair/disease progression. We previously showed that during development, Fgf10-positive cells located in the distal lung mesenchyme during the early pseudoglandular stage are progenitors for airway SMCs. In addition, We have reported that FGF signaling in the mesenchyme impairs the entry of the mesenchymal progenitors into the SMC lineage both in vitro and in vivo. Furthermore, we have shown that inactivation of beta-catenin in the mesenchyme leads to the loss of amplification of the mesenchymal progenitor cells due the loss of FGF9/FGFR2c signaling. We have also found that in the adult mice Wnt activation was triggered in airway SMC following naphthalene injury. Such increase in Wnt signaling is linked to increased mesenchymal cell proliferation and Fgf10 expression in these cells. Fgf10 in turn is instrumental for the repair of damaged bronchial epithelium. Moreover, we have reported that inhibition of beta-catenin signaling in the mesenchyme triggered by the silencing of miR142 leads to arrested proliferation and premature differentiation of the smooth muscle cells. Lineage tracing using our recently generated Fgf10CreERT2 knock in mice showed that Fgf10-positive cells in the embryonic lungs labeled at embryonic day (E) 11.5 are progenitors for smooth muscle cells (SMCs), resident mesenchymal stromal (stem) cells and lipofibroblasts. Lipofibroblasts (LIFs) found in the late fetal and postnatal lung parenchyma are juxtaposed to alveolar type II stem cells and have been proposed to contribute to the maintenance of their stemness. Although LIFs have been studied in postnatal lungs, their exact cellular origin and mechanism of differentiation are unknown. Our recent results demonstrate an essential role for Fgf10 signaling in directing the differentiation of Fgf10-positive cells towards the LIF lineage during late lung development.

32 Regulation of macroautophagy in amiodarone induced pulmonary fibrosis

Mahavadi P[1,7], Henneke I[1], Knudsen L[2,6], Venkatesan S[1], Ruppert C[1,7], Hegermann J[2,6], Liebisch G[3], Wrede C[2,6], Chambers R[4], Ochs M[2,6], Schmitz G[3], Vancheri C[5], Seeger W[1,7], Korfei M[1], Guenther A[1,7]

DOI: 10.1055/s-0034-1376801

Amiodarone (AD) is a highly efficient antiarrhythmic drug, however, it may cause interstitial pneumonia as well as lung fibrosis. Apoptosis of alveolar epithelial type II cells (AECII) has been suggested to play an important role in this disease, but the precise molecular mechanisms are unclear. Here, we aimed to establish a murine model of AD induced lung fibrosis and assess the role of autophagy. Intratracheal administration of AD induced extensive lung fibrosis, accumulation of surfactant phospholipids and surfactant proteins (SP) in mice. Induction of autophagy and apoptosis were encountered in AECII of AD treated mice over time. AD treated MLE12 and primary AECII showed increased proSP-C and LC3B positive vacuolar structures and underwent apoptosis in dependency of LC3B. In vitro, AD induced autophagosome-lysosome fusion and increased the autophagy flux. In vivo, LC3B was localized at the limiting membrane of lamellar bodies, which were closely connected to the autophagosomal structures in the AECII. Our data suggest that AD causes activation of macroautophagy, intracellular surfactant accumulation in the AECII and extensive AECII apoptosis, resulting in lung fibrosis.

33 Endogenous Fgfr2b ligands are dispensable for fibrosis formation and resolution in bleomycin-injured mice

MacKenzie B[1], Al Alam D[2], Henneke I[1], El Agha E[1], Quantius J[1], Chao CM[1], Wilhelm J[1], Königshoff M[3,6], Herold S[1,7], Klepetko W[4], Günther A[5,7], Seeger W[1,7], Bellusci S[1,7]

DOI: 10.1055/s-0034-1376802

Increased fibroblast growth factor 10 (Fgf10) expression in vivo and administration of exogenous FGF7 recombinant protein enhance lung repair due to bleomycin injury by sending survival signals to lung epithelial cells via tyrosine kinase fibroblast growth factor receptor 2b (Fgfr2b). Given the therapeutic effects of these ligands during bleomycin injury, we hypothesized that activation of the Fgfr2b endogenous pathway is critical for lung repair. Furthermore, as new studies for the treatment of Idiopathic Pulmonary Fibrosis (IPF) have begun to target tyrosine kinase receptors, we aimed to 1) assess the levels of FGF10 and FGF7 signaling in IPF lungs, and 2) assess the recruitment of the endogenous Fgfr2b pathway after bleomycin lung injury in mice. Though FGF7 and FGF10 transcripts were increased in IPF patient lungs, receptors as well as downstream targets were significantly decreased. In contrast, wild type mice undergoing spontaneous repair after bleomycin injury, expressed Fgf10 and downstream targets from 14 days post injury, indicating potential recruitment of this pathway during repair. Surprisingly, however, mice deficient in endogenous Fgfr2b signaling did not develop significantly more fibrosis than wild type animals. However, the dysregulated signaling observed in end-stage IPF lungs and the re-

cruitment of Fgf10 during bleomycin injury of wild type mice, may indicate the potential therapeutic use of exogenous FGF10 to promote fibrosis resolution in IPF patients.

34 Mitochondrial autophagy in the development of amiodarone induced pulmonary fibrosis

Venkatesan S[1], Chillappagari S[2], Henneke I[1], Seeger W[1], Günther A[1], Mahavadi P[1]
[1]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL); [2]Philipps University Marburg, Marburg
DOI: 10.1055/s-0034-1376803

Amiodarone (AD) is an anti-arrhythmic drug with very well-known vasodilatory properties. Severe pulmonary toxicity has been reported in patients receiving AD even at low doses, with the most common histological finding being chronic interstitial pneumonia. The precise mechanism underlying AD-induced pulmonary toxicity remains unknown. Dysfunctional mitochondria and enhanced oxidative stress via the production of reactive oxygen species (ROS) have been reported in AD-induced pulmonary toxicity. Recent unpublished studies from our group revealed AECII (Alveolar epithelial cells type II) specific autophagy alongside with AECII apoptosis and lysosomal stress in the lungs of AD treated mice and mouse lung epithelial (MLE) 12 cells. This convinced us to hypothesize that AD alters mitochondrial autophagy (mitophagy) and causes subsequent cell death, as an outcome of increased oxidative stress. Apart from the well-known autophagy markers like LC3BII, p62, ATG7, ATG12 – 5, important mitophagy markers like Pink and NIX/BNIP3L was significantly increased in AD treated mice lungs. In addition, PUMA, Bax and Cytochrome C, which are involved in mitochondrial dysregulation, were also elevated in response to AD treatment in mice lungs and in AECII. Hemeoxygenase-1 (HO-1), a pivotal antioxidant protein was increased in AD treated mice lungs, AECII and MLE12 cells. Since HO-1 forms a major link between oxidative stress and autophagy, we hypothesized that AD induced autophagy might be HO-1 dependent. In contrast, both in vitro knockdown (via siRNA) and chemical inhibition of HO-1 increased the levels of LC3BII. Similarly, LCB knockdown further increased the AD induced HO-1 protein levels in MLE12 cells. This indicates that AD induces HO-1 independent autophagy and HO-1 seems to be protective in function. We conclude that amiodarone induces mitochondrial autophagy, which might accelerate the apoptosis of AECII and thereby lung fibrosis in response to amiodarone treatment.

35 Integrative molecular and anatomical characterization of idiopathic pulmonary fibrosis

Wehling J[1,5], Kellner M[2,5], Izykowski N[1,5], Braubach P[1,5], Warnecke G[3,5], Knudsen L[2,5], Haverich A[3,5], Wiegmann B[3,5], Vogel-Claussen J[4,5], Kreipe H[1,5], Länger F[1,5], Kühnel M[2,5], Jonigk D[1,5]

DOI: 10.1055/s-0034-1376804

Rationale: Idiopathic pulmonary fibrosis (IPF) is a chronic, debilitating disease which is characterized by excessive collagen deposition and destruction of lung architecture leading to respiratory insufficiency. Lung transplantation still remains the only definite therapeutic option, since the etiology of IPF is poorly understood and no adequate medical treatment is currently available. In IPF there appears to be a correlation between the spatial localization of fibrotic changes and disease progression. The present study characterizes histopathological changes seen in IPF lungs with molecular changes and anatomical/three-dimensional distribution. **Methods:** Freshly explanted IPF lungs from patients undergoing lung transplantation were inflated and scanned by computer tomography to identify and sample representative areas of fibrotic reorganization. The internal structure of the samples was analyzed in three-dimensional datasets by using scanning laser optical tomography (SLOT). Subsequently, areas of interest were laser-microdissected and a set of fibrosis-associated genes and corresponding endogenous controls were analyzed by real-time PCR and immunohistochemistry. All results were correlated with the individual clinical findings. **Results:** The three-dimensional position of fibroblastic foci was visualized properly by using SLOT. An integrative model of IPF could be generated by correlating the 3D change patterns with the molecular microenvironment. **Conclusions:** Correlation of the techniques outlined above (CT, SLOT, microsropy, 3D reconstruction, laser-microdissection, RT-PCR and immunohistochemistry) with clinical changes enables us to characterize IPF on a macroscopic, microscopic and molecular level for the first time.

36 Development of a new mouse model to assess the therapeutic efficacy of GRP78 for prevention and resolution of ER stress in vivo

Henneke I[1], Ruppert C[1,2], Günther A[1,2], Korfei M[1]
[1]Justus-Liebig-University Gießen, Gießen; [2]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376805

It is known, that ER-stress plays a role in several, very different diseases like artherosclerosis, dilated cardiomyopathy or neurodegenerative diseases. Maladaptive ER-stress was also indicated to play a prominent role in IPF and seems to represent a key trigger in the pathogenesis of this disease. As 78kDa glucose-regulated protein/immunoglobulin-binding protein (Grp78/Bip) is the key chaperone of the ER, and as it has been shown to counterbalance ER stress-induced apoptosis induced by etoposide or proteasome inhibition in many cell lines in vitro, we plan to assess the therapeutic efficacy of GRP78/Bip for preventing and resolving ER stress in vivo. For this purpose we were generating transgenic mice with conditional overexpression of full-length GRP78 in alveolar epithelial type II cells (AECII). In detail, the cDNA encoding mmGrp781 – 654 was cloned into the pBI-L_Tet vector. After oocyte injection through a cooperation with EMBL (Dr. P. Moreira, EMBL Mouse Biology Unit; Campus A. Buzzati-Traverso, Monterotondo, Italy), breeding of heterozygous founders was performed, followed by crossbreeding with homozygous transactivator SP-C rtTA mice. The resulting double-transgenic mice with inducible conditional overexpression of Grp78 in AECII will be subjected to different models of lung fibrosis (Pepstatin A, Amiodarone and Bleomycin) with overexpression of GRP78 shut on or shut off. For induction of GRP78 overexpression double-transgenic mice will be fed with doxycycline enriched food (Tet-On). Age-matched animals with the transgene being shut off (Tet-Off) will serve as controls. We suggest, that GRP78 overexpressing mice will be protected from ER stress and subsequent development of lung fibrosis and that this mouse model will provide insight into the mechanism by which Grp78 overexpression protects from ER stress and lung fibrosis induced by DNA damage and oxidative stress (bleomycin-model) or induced by accumulated proSP-B precursors (Amiodarone- and Pepstatin A-model).

37 Biological role of the proapoptotic transcription factor C/EBP homologous protein (CHOP) in Idiopathic Pulmonary Fibrosis (IPF)

Klymenko O[1], Henneke I[1], Ruppert C[1,2], Seeger W[1,2], Guenther A[1,2], Korfei M[1]
[1]Justus-Liebig-University Gießen, Gießen; [2]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376806

We have recently identified severe and pro-apoptotic Endoplasmic Reticulum (ER) stress as major pathomechanism for alveolar epithelial cell (AEC) injury in Idiopathic Pulmonary Fibrosis (IPF). In line with this, the pro-apoptotic transcription factor CHOP, which functions as a crucial mediator of ER stress-induced apoptosis, was strongly induced in AECII from patients with IPF. We therefore aimed to fully disclose the transcriptional regulation and biological role of epithelial CHOP expression in AECII-like cells in vitro, and in pulmonary fibrosis in vivo. We performed promotor analysis of the human CHOP gene in silico, followed by reporter gene assays for several proximal CHOP promoter fragments in A549 and MLE12 cells in the presence or absence of ER stress-inducing agents. We performed transient overexpression of FLAG- and c-myc-tagged CHOP constructs in alveolar epithelial cell lines A549 (human) and MLE12 (murine), followed by the assessment of CHOP expression and post-translational modification and regulation of apoptosis. The in silico-analysis of the 2.7-kb 5'-flanking region of the human CHOP gene revealed approximately 15 different putative transcription factor bind-

ing sites in addition to the already known ER stress-response elements (ERSE) and Amino-Acid-response elements (AARE). Surprisingly, next to the common transcription factor binding sites (ERSE and AARE), the CHOP promoter has another transcription factor binding site(s) which seems to play a role in CHOP expression. Additionally, CHOP could be successfully overexpressed in MLE12 and A549 cells, with a maximum of protein expression 24 – 48 hours after transfection. Parallel to the expression of CHOP, caspase-3 activation and hence induction of apoptosis could be encountered in these cell lines. Moreover, overexpression studies suggest the presence of unknown post-translational modifications in CHOP proteins. Based on the data generated herein, we expect to be able to develop novel, AECII specific, antiapoptotic treatment strategies for treatment of IPF.

38 Deficient Autophagy in Hermansky-Pudlak Syndrome associated lung fibrosis

Ahuja S[1], Henneke I[1], Knudsen L[2,4], Gochuico BR[3], Ruppert C[154], Ochs M[2,4], Korfei M[1], Seeger W[1,5], Guenther A[1,5], Mahavadi P[1]
[1]Justus-Liebig-University Gießen, Gießen; [2]Hannover Medical School, Hannover; [3]National Institute of Health, USA; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [5]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376807

Hermansky-Pudlak syndrome (HPS) is a lysosome realated disorder. Patients with HPS types -1, -2 & -4 develop pulmonary fibrosis called Hermansky-Pudlak syndrome associated Interstitial Pneumonia (HPSIP). HPSIP lungs show enlarged alveolar type II cells (AECII) with giant lamellar bodies. We previously reported lung fibrosis in a HPSIP mouse model (HPS 1/2), accompanied with surfactant accumulation and apoptosis of AECII due to severe lysosomal stress and ER stress. Data from human HPS 1 patient corroborated with the HPS 1/2 mice data. Here, we aim to analyze autophagy, an important lysosomal degradation pathway, under HPSIP conditions. Immunohistochemistry was performed and on serial paraffin lung sections from HPS 1, HPS 2, HPS 1/2 and WT control mice and on lung sections from human HPS 1 patients and healthy donors for autophagy related proteins LC 3B, p62 and TFEB and for AECII marker, pro SP-C. Immunogold labelling for LC 3B was performed on mice lungs fixed in paraformaldehyde and gluteraldehyde. Immunohistochemistry revealed that the AECII of HPS 1/2 mice and human HPS 1 did not stain for LC 3B, while a convincing signal was observed within macrophages of the same sections and within AECII & macrophages of WT mice and healthy donors. Electron microscopy results confirm the qualitative observation of less labeling of LC 3B on the limiting membrane of lamellar bodies in HPS mice compared to WT mice. Immunohistochemistry showed decreased staining for p62 and TFEB within AECII of HPS 1/2 compared to WT mice. Our results point towards defective autophagy within AECII under HPSIP conditions both in mice and men. An in depth analysis of this pathway is underway to further understand the role of defective autophagy in the development of HPSIP.

39 Role of Bcl-xL in hepatocyte growth factor-elicited epithelial protection in idiopathic pulmonary fibrosis

Skwarna S[1], Henneke I[1], Seeger W[1], Geiser T[2], Günther A[1], Ruppert C[1]
[1]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen; [2]Department for Pulmonary Medicine Inselspital, Bern, Switzerland
DOI: 10.1055/s-0034-1376808

Hepatocyte growth factor (HGF) is a cytokine with pleiotropic functions during wound healing and repair. Its anti-fibrotic effects were shown in animal models of lung fibrosis and linked to improved cellular survival and proliferation and reduced myofibroblast accumulation. HGF-elicited, pro-survival pathways have yet not been investigated in detail in lung epithelial cells. Based on literature, our study is focused on Bcl-xL, pro-survival protein involved in mitochondrial control of apoptosis. Analysis of IPF lung homogenates revealed significantly increased expression of Bcl-xL when compared to donor lungs. In human IPF, much less in donor lungs, Bcl-xL protein is highly expressed in hyperplastic alveolar epithelial type II cells, basal cells and bronchial epithelial cells. Furthermore, Bcl-xL expression co-localized with specific HGF receptor c-Met. In vitro data shows decreased expression of Bcl-xL in murine epithelial MLE12/15 cells in response to oxidative stress-induced apoptosis. Under these conditions, HGF treatment resulted in increased survival of cells that correlated with increased Bcl-xL expression. The same effect of HGF is seen after treatment of cells with the potent ER-stress inducer thapsigargin. Anti-apoptotic effect of HGF was abolished after pre-incubation with c-Met inhibitor. Knock-down of Bcl-xL protein made epithelial cells much more sensitive to injury caused by oxidative stress, as well as ER stress, however did not affect HGF pro survival activity. In conclusion, our data shows that HGF has a strong pro-survival effect on alveolar epithelial cells. Its interdependency with Bcl-xL protein needs to be further investigated, however Bcl-xL seems to be an important factor in epithelial response to injury.

40 Alveolar derecruitment and collapse induration as crucial mechanisms in lung injury and fibrosis

Lutz D[1], Gazdhar A[2], Lopez-Rodriguez E[1], Mahavadi P[3], Günther A[3,7], Klepetko W[4], Bates JH[5], Smith B[5], Geiser T[2], Ochs M[1,6], Knudsen L[1,6]
[1]Hannover Medical School, Hannover; [2]University of Bern, Bern, Switzerland; [3]Justus-Liebig University Gießen, Gießen; [4]Medical University of Vienna, Vienna, Austria; [5]University of Vermont College of Medicine, Vermont, USA; [6]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [7]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376809

Idiopathic pulmonary fibrosis (IPF) and bleomycin-induced pulmonary fibrosis are associated with surfactant system dysfunction, alveolar collapse, and collapse induration (irreversible closure). These events play critical but undefined roles in the loss of lung function and disease progression. To quantify how surfactant inactivation leads to lung injury and fibrosis we employed design-based stereology and invasive pulmonary function tests 1, 3, 7, and 14 days (D) following intratracheal bleomycin-instillation in rats. Active surfactant subtypes declined significantly by D 1, leading to progressive alveolar closure (derecruitment) and an associated decrease in organ-scale compliance. Alveolar epithelial damage was more pronounced in closed alveoli compared to ventilated alveoli. At the ultrastructural level, we observed collapse induration in the bleomycin treated rats on D 7 and D 14 as indicated by collapsed alveoli overgrown by a hyperplastic alveolar epithelium. This pathophysiology was also observed for the first time in human IPF lung explants. Prior to the onset of collapse induration (D 7), the lungs were easily recruited, and lung elastance could be kept low after recruitment by application of positive end-expiratory pressure (PEEP). By contrast, at later time points the recruitable fraction of the lung was reduced by collapse induration, causing elastance to be elevated at high levels of PEEP. We conclude that surfactant inactivation leading to alveolar collapse and subsequent collapse induration is the primary pathway for the loss of alveoli in this animal model and is the dominant factor in the degradation of lung function. Our ultrastructural observations suggest that collapse induration is also important in human IPF.

41 Wnt-Heparan Sulfate Proteoglycan interaction in fibrotic lung disease

Vierkotten S[1], Aumiller V[1], Uhl F[1], Königshoff M[1]

DOI: 10.1055/s-0034-1376810

Introduction: Idiopathic pulmonary fibrosis (IPF) is a lethal lung disease of yet unknown etiology. Recently, (re)activation of developmental pathways, such as Wnt/β-catenin in the alveolar epithelium has been linked to disease development. Regulation of Wnt/β-catenin activation has been shown to be dependent on Heparan Sulfate Proteoglycans (HSPGs). The role of Wnt-HSPG interaction in IPF, however, remains to be elusive.
Methods: Murine and human lung epithelial cells were treated with Heparin, Desulfated (DS) Heparins or Heparinase II and Chondroitinase ABC, respectively. A Heparin binding assay was used to assess binding of Wnt3a to Heparin and DS Heparins. Immunofluorescence staining of ex vivo lung tissue for Wnt proteins was conducted. In addition, lung tissue

and bronchoalveolar lavage fluid (BALF) from bleomycin-treated mice were screened for Wnt ligand expression. **Results:** WNT3a is localized to bronchial and alveolar epithelial cells with increased expression in fibrotic regions. Canonical WNT3a and WNT10b levels are elevated in bronchoalveolar lavage fluid (BALF) of mice with bleomycin-induced lung fibrosis. Immunofluorescence staining of ex vivo lung tissue slices revealed upregulated WNT3a expression in bleomycin-treated mouse lungs compared to controls. Heparin treatment of murine lung epithelial cells resulted in inhibition of TOP/FOP-flash reporter, indicating decreased canonical WNT signaling. In contrast, Heparinase II and Chondroitinase ABC treatment resulted in upregulated β-catenin-dependent gene transcription. Interestingly, 6-O-DS Heparin treatment of A549 cells did not decrease WNT signaling, while binding of WNT3a to 6-O-DS Heparin was not altered, thereby suggesting less inhibition of WNT signaling upon binding to 6-O-DS Heparin. **Conclusion:** Taken together, our findings revealed that HS sulfation and degradation modulate WNT/β-catenin signal activity. Altered sulfation states during extracellular matrix (ECM) remodeling in IPF pathology might contribute to (re)activation of developmental pathways like WNT/β-catenin.

42 Novel alveolar epithelial cell differentiation markers in lung injury and repair

Mutze K[1], Uhl F[1], Milosevic J[2], Eickelberg O[1], Königshoff M[1]
[1]Comprehensive Pneumology Center München (CPC-M), Helmholtz Zentrum München, Member of the German Center for Lung Research (DZL), Munich; [2]Simmons Center for Interstitial Lung Disease/University of Pittsburgh Medical Center
DOI: 10.1055/s-0034-1376811

Objective: The alveolar epithelium, consisting of mainly alveolar epithelial type 1 (AT1) and type 2 (AT2) cells, represents a major site of tissue destruction in idiopathic pulmonary fibrosis. Several studies indicate that adult AT2 cells are able to self-renew and exert progenitor function for AT1 cells upon alveolar injury in vivo. However, cell differentiation pathways enabling this plasticity are poorly understood. Here, we used the primary culture of murine AT2 cells as model system to identify novel proteins and pathways involved in epithelial transdifferentiation. **Methods/Results:** Expression profiles of primary transdifferentiating AT2 cells were analyzed applying 2D gel electrophoresis and mass spectrometry. Beside others, we found enolase 1 (ENO1) to be upregulated, whereas carbonyl reductase 2 (CBR2) was decreased in transdifferentiating AT2 cells, as further confirmed by quantitative RT-PCR analysis and immunoblotting. This was accompanied by reduction in AT2 cell derived pro surfactant protein C (proSPC) expression and increased AT1 cell T1a expression, as well as an activation of the Wnt/β-catenin pathway. We applied a lung tissue culture model of murine precision cut lung slices ex vivo to further analyze transdifferentiation in the 3D natural spatial lung environment. We observed Wnt/β-catenin signal activation and alveolar epithelial cell transdifferentiation upon lung tissue cultures ex vivo. Interestingly, the inhibition of Wnt/β-catenin signaling in cultured AT2 resulted in decreased expression of ENO1 and T1a and stabilization of CBR2. In an in vivo model of lung fibrosis, which exhibits activated Wnt/β-catenin signaling, decreased expression of CBR2 and proSPC correlated in AT2 cells, whereas ENO1 along with T1a expression was increased. **Conclusion:** Proteomic analysis revealed novel proteins differentially expressed in differentiating AT2 cells. Interestingly, newly identified proteins were regulated by β-catenin in vitro and in experimental fibrosis in vivo, suggesting a role in epithelial repair processes upon lung injury.

43 In vivo effects of TGF-β1 in lung surfactant regulation, lung meachanics amd structure

Lopez-Rodriguez E[1,5], Boden C[1], Knippenberg S[1,5], Pascual A[2], Perez-Gil J[2], Kolb M[3], Gauldie J[4], Maus U[1,5], Ochs M[1,5], Knudsen L[1,5]
[1]Hannover Medical School, Hannover; [2]Complutense University Madrid, Madrid, Italy; [3]McMaster University,Hamilton, Canada; [4]McMaster University,Hamilton, Canada; [5]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376812

Transforming growth factor beta 1 (TGF-β1) is a signalling protein with a wide range of biological activities. TGF-β1 is thought to have a pivotal role in fibrogenesis, where TGF-β1 induces myofibroblast migration and increases extracellular matrix synthesis, including collagen. Moreover, it has been described that TGF-β1 is a negative modulator of the regulation of surfactant associated proteins A (SP-A), B (SP-B) and C (SP-C) in vitro. Pulmonary surfactant is a lipid-protein complex that lowers surface tension at the respiratory air-liquid interface, stabilizing the lungs against physical forces tending to collapse alveoli. SP-B and SP-C deficiency has been found in patients suffering from lung diseases and related to potential mechanical stress of the lung epithelium. We have characterized lung surfactant protein composition 1 and 2 weeks after adenoviral mediated gene transfer of active TGF-β1 into lungs. Gene expression of surfactant proteins is down-regulated pointing at deficient transcriptional regulation that might include a deficient activity of TTF-1, during TGF-β1 overexpression. Deficiency on SP-B and SP-C at early stages correlates with high surface tension under dynamic cycling of isolated surfactant in Captive Bubble Surfactometry (CBS). In addition, high surface tension correlates with decreased quasistatic lung compliance and increased collapsibility of distal airspaces. Stereological data demonstrate a correlation between septal wall thickness and quasistatic compliance 2 weeks after gen-transfer. At the ultrastructural level thickening of septal walls, could be attributed to an increase in interstitial cells, formation of dense alveolar oedema and increase in profiles of epithelial type II (AEII) cells. The latter could be also attributed to Epithelial to Mesenchymal Transition (EMT), indicated by down-regulation of epithelial markers associated to up-regulation of mesenchymal molecular markers. We can conclude that in vivo TGF-β1 is a strong negative regulator of surfactant metabolism, originating a mechanical stress that may contribute to EMT at following stages.

44 Effect of stretch and hyperoxia on the stress response of the newborn mouse lung

Geisler I[1], Gimm T[1], Oak P[1], Koschlig M[1], Ballweg K[1], Meiners S[1], Hilgendorff A[1]
[1]Comprehensive Pneumology Center München (CPC-M), Helmholtz Zentrum München, Member of the German Center for Lung Research (DZL), Munich
DOI: 10.1055/s-0034-1376813

Introduction: Prolonged mechanical ventilation of preterm infants with oxygen-rich gas (MV-O2) as a lifesaving treatment often leads to chronic lung disease, also known as bronchopulmonary dysplasia (BPD). The disease is characterized by extracellular remodelling and inflammatory changes leading to impaired alveolar and vascular development. We aimed at investigating the effect of MV-O2 on the protein stress response of the immature lung focussing on cellular protein quality control pathways such as ER-stress, autophagy and proteasome function using a mouse-model of mechanical ventilation and neonatal pulmonary myofibroblasts (MFBs) which are treated with stretch, TGF-β, or hyperoxia in vitro. **Materials and Methods:** 5 – 7 days old C57BL/6 mice were ventilated at 180 breaths/min with/without oxygen (FiO2 = 0.4 or FiO2 = 0.21) for 2 or 8 hours; the controls spontaneously breathed room air or O2 for 2 or 8 hours. At the end of each experiment, lungs were harvested in liquid nitrogen; homogenized lysate was used for protein- and RNA analysis. For in vitro analysis, MFBs were isolated from lungs of 5 – 7 day old mice and subjected to stretch or hyperoxia experiments with/without TGF-β treatment for 24 hours. **Results:** Preliminary results demonstrate a 1.5 fold increase in ER-stress (Binding immunoglobulin protein) and a significant decrease in cell-proliferation (Proliferating Cell Nuclear Antigen) in the ventilated lungs when compared to unventilated control littermates. Other stress response systems were not found to be significantly regulated in contrast to findings from

adult lung tissue. **Conclusion:** Our preliminary results indicate that the cellular protein quality control system in the neonatal lung shows a specific response to stress induced by mechanical stretch and hyperoxia. Ongoing experiments using different markers and functional assays will characterize this response in more detail.

Disease Area: Pulmonary Hypertension

45 P66shc deficient mice develope decreased right heart hypertrophy via a Cyclophilin D dependent mechanism in hypoxia-induced pulmonary hypertension

Gierhardt M[1], Sommer N[1], Schreckenberg R[2], Schlueter KD[2], Ghofrani AH[1], Schermuly RT[1], Schulz R[2], Weissmann N[1]
[1]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen; [2]Institute of Physiology
DOI: 10.1055/s-0034-1376814

In acute and chronic hypoxia the response of the pulmonary vasculature is suggested to be regulated via mitochondrial reactive oxygen species (ROS). In response to cellular stress the mitochondrial regulator protein p66shc enhances the ROS-production probably via the pro-apoptotic protein cyclophilin D (CypD). We hypothesized in p66shc-deficient mice lower hypoxic pulmonary vasoconstriction (HPV) and pulmonary hypertension (PH) related to lower hypoxia-induced ROS-production. HPV was determined in isolated lungs of p66shc and CypD deficient mice, as well as in mice lacking both proteins, and compared to lungs of wild type (WT) mice. The thromboxane mimetic U46619 and potassium chloride (KCl) were used as hypoxia-independent vasoconstrictive stimuli. PH was quantified after exposure of mice to 10% oxygen for 4 weeks by in vivo hemodynamics, and morphometric analysis. Mice deficient of p66shc, CypD or both proteins exhibited lower responses to acute hypoxia, U46619 and KCl compared to WT mice. In chronic hypoxia-induced pH only p66shc deficient mice exhibited lower right ventricular pressure, right ventricular hypertrophy and hematocrit compared to WT mice. In mice lacking CypD or both proteins, no significant changes of these parameters in chronic hypoxia were detected. There was no change in lung remodeling between all groups. We conclude that the mitochondrial ROS producing protein p66shc regulates right heart hypertrophy and right ventricular pressure during chronic hypoxia, probably via a CypD dependent mechanism.

46 A possible role of serotonin for the development of tobacco smoke-induced lung emphysema and pulmonary hypertension

Pichl A[1], Seimetz M[1], Fysikopoulos A[1], Bednorz M[1], Parajuli N[1], Haag D[1], Reiter R[2], Grimminger J[1], Seeger W[1], Schermuly R[1], Grimminger F[1], Ghofrani HA[1], Weissmann N[1]
[1]Excellencecluster Cardio-Pulmonary System (ECCPS), Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Justus-Liebig-University, Gießen; [2]Ergonex Pharma GmbH, Switzerland
DOI: 10.1055/s-0034-1376815

Chronic obstructive pulmonary disease (COPD) is a major cause of death and disability worldwide. An estimated portion of 30 – 70% of COPD patients also suffer from pulmonary hypertension (PH). Studies indicate that activation of serotonin-mediated pathways contribute to development of PH. Moreover, vascular alterations have been suggested to contribute to emphysema development. The aim of the study was to clarify the role of serotonin and the serotonin inhibitor Terguride on the development of tobacco smoke-induced emphysema and PH in a mouse model. WT mice (C57BL6/J) were exposed to cigarette smoke for 6 hours/day, 5 days/week for 8 months. Mice were split into different experimental groups (Placebo smoke-exposed, Placebo non-exposed and Terguride smoke-exposed). Terguride-treated animals received the drug twice per day by gavage. Gene and protein expression analysis were performed by quantitative real-time PCR and western blotting. Development of PH and emphysema were determined by measurement of lung compliance, in vivo hemodynamics, right ventricular heart mass alterations and as well by alveolar and vascular morphometric analyses. The mRNA as well as protein analyses revealed a significant upregulation of 5-HT2A and 5-HT2B receptors in tobacco smoke-exposed mice. Similar alterations were found in lungs from human COPD patients compared to healthy donors. Non-treated smoke-exposed mice developed pulmonary hypertension and emphysema upon smoke exposure. In contrast, smoke-exposed Terguride-treated mice were prevented from PH and vascular remodeling. In addition, the smoke-induced increase in lung compliance as well as structural measures for emphysema development remained on a normal level in Terguride-treated smoke-exposed mice. We concluded that Terguride has a protective effect on the development of tobacco smoke-induced pulmonary hypertension and emphysema development in mice.

47 Arachidonic acid/cytochrome p450-derived mediators decrease hypoxic pulmonary vasoconstriction in isolated, ventilated and perfused mouse lungs

Erb A[1], Peters DM[1], Schermuly RT[1], Heipel M[1], Bier J[1], Quanz K[1], Seeger W[1], Grimminger F[1], Weißmann N[1], Kiss L[1]
[1]Justus-Liebig-University Gießen; Excellencecluster Cardio-Pulmonary System (ECCPS); Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376816

Introduction: Hypoxic pulmonary vasoconstriction (HPV) is an essential physiological mechanism that adapts perfusion to ventilation to optimize gas exchange by redistributing the blood flow to well-ventilated areas, thereby improving alveolar oxygenation. Disturbances in HPV can lead to life-threatening hypoxemia. Intrinsic and modulatory pathways of HPV are not fully elucidated. Arachidonic acid-derived mediators are known to be potent vasoregulators in different organs in health and disease. In the lung, little is known about the role and physiological function of arachidonic acid/cytochrome p450-derived mediators. Our study focuses on the cytochrome p450 oxygenase pathway, during which 20-hydroxyeicosatetraenoic acid (20-HETE) and epoxyeicosatrienoic acids (EETs) are synthezised. The aim of this study was to investigate the effect of four EETs (5,6-, 8,9-, 11,12- and 14,15-EET) and 20-HETE on HPV. **Methods:** Experiments were performed in isolated, ventilated and perfused lungs of wild-type mice. The strength of HPV in response to a change from normoxic to hypoxic ventilation (21% O2 and 1% O2, 10 minutes) was quantified. The effect of EET- and 20-HETE-applications on acute HPV and normoxic vascular tone was compared to control experiments with solvent applications. **Results:** Application of EETs did not affect normoxic pulmonary vascular resistance. However, hypoxia-induced vasoconstriction was significantly reduced in response to application of 5,6-, 8,9-, 11,12- and 14,15-EET via the perfusate. Application of 20-HETE induced vasoconstriction during normoxia and inhibited subsequent hypoxic pulmonary vasoconstriction. **Conclusion:** EETs as well as 20-HETEs influence hypoxic pulmonary vasoconstriction (HPV) via different mechanisms. Future studies with stereoisomers of EETs as well as with inhibitors for EET synthezising enzymes will give further insight into EET-mediated pulmonary vasoregulation.

Disease Area: Endstage Lung Disease

48 Treatment with donor specific alloantigen 28 days before or on the day of lung transplantation – a comparison in a large animal model

Jansson K[1,3], Sommer W[1,3], Avsar M[1], Salman J[1], Knöfel AK[1,3], Hahn J[1,3], Hewicker-Trautwein M[2], Jonigk D[1,3], Falk C[1], Haverich A[1,3], Warnecke G[1,3]
[1]Hannover Medical School, Hannover; [2]Veterinary School Hannover, Hannover; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376817

Purpose: Administration of donor-specific alloantigen during transplantation has been shown to induce T-cell regulation and long term transplant tolerance in our large animal model before. In rodents, it was also possible to induce allograft acceptance if the donor-antigen was administered 28 days in advance. Here, we wished to translate this protocol into our lung transplantation model in minipigs and compare it to our already established protocols. **Methods:** Lung transplantation from MHC-mismatched donors was performed in 41 minipigs. 23 of those animals received donor-splenocytes perioperatively (group1), whereas in 18 animals the splenocytes were administered 28 days before transplantation (group2). All animals were treated with Tacrolimus and Ster-

oids 28 days following transplantation. Concomittant with donor-antigen the animals received either non-myeloablative irradiation or depleting anti-CD4 and/or -CD8 antibodies. Both groups include 4 (group1) respectively 6 (group2) animals which underwent no immunomodulation at all. **Results:** In our minipig model, it was not possible to induce reliable allograft acceptance if the minipigs were treated with donor-antigen 28 days before transplantation. From the total of group2, only 16.7% achieved long term allograft survival (> 178 d), compared to group1 with 26.1% after all. After censoring animals that died due to other causes related to this experiment than rejection (like bleeding from thrombocytopenia) there still remained 73.3% animals with rejection in group2 but only 46.4% in group1 before postoperative day 178 (p = 0.01). Median survival in the day -28 animals was 64 days, whereas in the perioperatively treated animals it was 239 days. Time course and histology suggest sensitization and consecutive hyperacute rejection in animals pretreated with donor-splenocytes 28 days before lung transplantation even though anti-CD4 and/or -CD8 antibodies were co-administered. **Conclusion:** Administration of donor-splenocytes 28 days before transplantation appears to rather promote sensitization, but at the time of transplant promotes tolerance in this large animal lung transplantation model.

49 Towards the development of a bioartificial lung – Endothelialisation of TiO2 coated oxygenator membranes

Pflaum M[1,3], Kauffeldt M[2], Wiegmann B[1,3], Schmeckebier S[1,3], Korossis S[1,3], Schein J[2], Haverich A[1,3]
[1]Medical School Hannover, Hannover; [2]University of Federal Armed Forces Munich, Munich; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376818

Introduction: Currently, the use of extra corporeal membrane oxygenation (ECMO) devices, which is indicated for patients awaiting lung transplantation, is limited to a few weeks only, due to thrombus formation and deposition of blood components within the device. Therefore, the basic idea is to improve the haemocompatibility by endothelialisation of the poly-4-methyl-1-pentene gas exchange membranes (PMP), which necessitates the development of coating techniques for the mediation of endothelial cell adhesion to the hydrophobic polymers. The pulsed vacuum cathodic arc plasma deposition (PVCAPD) technique has been shown to enable the coating of thermosensitive polymers. Hence the eligibility of Titaniumoxides (TiO2) deposited on PMP using PVCAPD as an effective coating technique for enabling the endothelialization was assessed. **Methods:** PMP film samples were coated with TiO2 via PVCAPD and analyzed using SEM and EDX. Umbilical cord blood derived endothelial cells (hCBECs) were seeded on such samples and incubated for 24 h. Established monolayers were investigated for expression of activation-relevant marker genes and subjected to a leucocyte adhesion assay. Flow resistance and self-healing capacity were assessed in a laminar flow chamber applying 30 dyne/cm2 for 24 h. **Results:** SEM and EDX analysis confirmed the homogeneous deposition of nanoscalic TiO2 particles. hCBECs exclusively adhered to areas of PMP film coated with TiO2. Gene expression analysis revealed that endothelial cells seeded on TiO2 coated surface retained the non-activated, anti-thrombogenic state, additionally confirmed by a leucocyte adhesion assay. Furthermore, the established monolayer was resistant to high physiologic shear rate of 30 dyne/cm2, for 24 hours. Besides planar PMP, the coating technique was successfully applied to 3D hollow fibres where ECs established confluent monolayers. **Conclusion:** This study demonstrated that TiO2 coating via PVCAPD is a promising technique for coating thermo-sensitive PMP gas exchange membranes, enabling the generation of a non-activated and flow-resistant EC monolayer.

50 Do B-cells contribute to experimental Bronchiolitis obliterans syndrome?

Reichert M[1], Atanasova S[1], Fuchs-Moll G[1], Petri K[1], Padberg W[1,2], Grau V[1,2]
[1]Laboratory of Experimental Surgery, Department of General and Thoracic Surgery, Justus-Liebig-University Gießen, Gießen; [2]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376819

Objectives: Recently, we established a clinically relevant experimental model for human bronchiolitis obliterans syndrome (BOS), which involves orthotopic transplantation of rat lung allografts followed by intratracheal application of lipopolysaccharide (LPS) (Atanasova et al. 2013, J Heart Lung Transplant 32: 1131). Chronic lung damage does neither develop in allografts treated with vehicle instead of LPS nor in pulmonary isografts. Alloreactive and autoreactive antibodies have been detected in BOS patients but their pathogenic role is disputed. Here, we investigate B cell infiltration into experimental lung allografts as well as deposition of immunoglobulins and C4d. **Material and methods:** Orthotopic left lung transplantation was performed in the Fischer 344 to Lewis strain combination followed by application of ciclosporine (5 mg/kg) for 10 days. Lewis rats served as isograft recipients. Four weeks after transplantation, LPS (0.5 mg/kg body weight) was instilled into the trachea. Lungs were harvested before (day 28) and after LPS application (days 29, 33, and 40) for immunohistochemistry. **Results:** Perivascular and peribronchiolar areas of lung allografts were more strongly infiltrated by B cells in comparison to right native lungs and isografts. Interestingly, an influx of B cells into the alveolar region was induced in response to LPS-application only in allografts. Immunoglobulin-positive cells were markedly increased in the alveolar space of lung allografts compared to isografts at days 33 and 40. C4d deposits were mainly found in the wall of small blood vessels as well as on the respiratory epithelium of lung allografts but not of isografts. **Conclusion:** These results suggest that B cells play a role in the development of BOS by producing antibodies against donor tissue. As described before for renal allograft rejection, deposition of C4d could be a prognostic factor for lung allograft survival. Founding: DFG No. GR 1094/6 – 1

51 Interleukin 18 in the pathogenesis of experimental bronchiolitis obliterans syndrome (BOS)

Zakrzewicz A[1], Rabin L[1], Fischer A[1], Padberg W[1], Grau V[1,2]
[1]Laboratory of Experimental Surgery, Department of General and Thoracic Surgery, Justus-Liebig-University Gießen, Gießen; [2]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376820

Introduction: Bronchiolitis obliterans syndrome (BOS), characterized by bronchiolitis obliterans, vascular remodeling and general fibrosis is a major cause of mortality after lung transplantation. Elevated levels of IFNγ-dependent chemokines are predictive factors for the development of BOS. IFNγ expression can be induced by IL18, a pro-inflammatory cytokine, secreted mainly by macrophages upon inflammasome activation. IL18 can be involved in the remodeling of airways and vessels, fibrosis and impairment of endothelial progenitor cell function. However, its potential contribution to BOS has not been yet assessed. **Material and Methods:** The Fischer 344 to Lewis rat strain combination was used for orthotopic left lung transplantation. Isogenic transplantations were performed in Lewis rats. Recipients were treated with ciclosporine for 10 days and 28 days after transplantation, LPS was instilled into airways. The mRNA and protein expression of IL18 was measured on days 28, 29 and 33 after transplantation by quantitative RT-PCR and western blot, respectively. **Results:** Left lung isografts and allografts as well as control right lungs expressed stable mRNA levels of pro-IL18, whereas pro-IL18 protein was elevated in left lung allografts on days 28 and 29. Interestingly, mature form of IL18 was detected predominantly in left allografts on day 29 and was absent in right control lungs independent on the day investigated. In agreement with this observation, mRNA expression of inflammasome components like caspase1 and ASC was elevated in left allografts on day 29. **Conclusions:** IL18 might play important role in the development of BOS. Control of inflammasome activation and IL18 secretion might represent a novel therapeutic strategy to prevent lung graft destruction.

52 Simulation of physiologic conditions in diseased lung grafts for drug exposition using the Organ Care System – a new model

Sommer W[1,2], Hoeper MM[1,2], Kühn C[1,2], Tudorache I[1], Avsar M[1], Jonigk D[1,2], Länger F[1,2], Haverich A[1,2], Welte T[1,2], Warnecke G[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376821

The only curative treatment option for patients with end-stage lung disease is lung transplantation, since no curative pharmacological drug for diseases is known so far. In order to analyze the effect of new drugs on diseased tissue and vasculature, we developed an ex vivo lung perfusion (EVLP) setup, in which explanted diseased lungs from lung transplant recipients cab be treated with new drugs whilst undergoing normothermic perfusion and ventilation. Here, we present data from our first three lungs, that were put on EVLP in order to proof the feasibility of the experimental setup. **Methods:** For EVLP, the Organ Care System (OCS) a transportable EVLP unit with integrated ventilator was used. During transplant procedure, the diseased lungs of three end-stage IPF patients were explanted, leaving a sufficient cuff of the pulmonary artery as well as the main bronchus. Reperfusion was performed with ~1.0 – 1.2 l/min and ventilation was started aiming for a tidal volume of 250 – 300 ml, in respect to patient's body height and lung size. **Results:** The lungs were kept in the OCS for 17, 24 and 26 hours in order to test the longest possible conservation period in the perfusion unit. After cessation of EVLP, the lungs were preserved with formaline flush through the pulmonary artery. Histological examination showed characteristic histological features of the known underlying disease. More importantly, there was no visible difference between OCS-treated organs and untreated organs regarding tissue vitality. All OCS-treated grafts were free of histopathological correlates indicating necrosis, lysis or apoptosis. **Conclusion:** For that reason, OCS treatment reliably protects lung tissue and keeps it in a vital state. This observation was independent from the duration of OCS treatment. This new tool can now be used for testing drugs for end stage lung diseases with the opportunity of finding histopathological effects on lung tissue and/or vasculature.

53 Generation of a NKX2.1 knockin human induced pluripotent stem cell reporter line for monitoring the generation of respiratory cells

Weinreich S[1,2], Haller R[1,2], Ulrich S[1,2], Mauritz C[1,2], Martin U[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376822

One promising therapeutic option to cure hereditary pulmonary diseases like cystic fibrosis might be a cell replacement therapy comprising the generation of patient specific autologous induced pluripotent stem cells (iPSCs), followed by the correction of the genetic mutation, differentiation into the needed airway cell type and replacement of the endogenous cells. For long term restoration, most likely airway progenitor or stem cells like basal cells or submucosal gland duct stem cells will be required. A prerequisite is the development of an efficient and robust protocol for the generation of the desired airway stem cells from human iPSCs (hiPSCs). The transcription factor NK2 homeobox1 (NKX2.1) is expressed in lung epithelial progenitor cells which can give rise to airway stem cells. Thus, NKX2.1 represents a suitable marker for optimizing differentiation protocols. The aim of the present study was the generation of a hiPSC reporter line targeting the NKX2.1 locus. Therefore, two hiPSC lines, established in our lab, were screened for efficient differentiation into definitive endoderm and NKX2.1 expressing cells. Based on the results, the hHSC_F1285_T-iPS2 line was then used for the transfection with the NKX2.1 targeting vector (kind gift of Andrew G. Elefanty), which consists of two homology arms for homologous recombination flanking an eGFP coding sequence and a floxed antibiotic selection cassette. One correctly targeted clone out of 191 neomycin resistant clones was identified by PCR analysis. Southern blot analysis using an eGFP probe verified that the vector had integrated correctly into one of the two NKX2.1 alleles without any further integration sites. Differentiation of the identified clone with our established protocol resulted in eGFP expressing cells first occurring on day 12 of differentiation. The established hiPSC NKX2.1 reporter line represents an optimal tool for the improvement of protocols for the pulmonary differentiation of hiPSCs.

54 Changes in local alpha-1-antitrypsin expression during the pathogenesis of experimental bronchiolitis obliterans syndrome

Siebers K[1], Atanasova S[1], Reichert M[1], Padberg W[1,2], Grau V[1,2]
[1]Laboratory of Experimental Surgery, Department of General and Thoracic Surgery, Justus-Liebig-University Gießen, Gießen; [2]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL), Gießen
DOI: 10.1055/s-0034-1376823

Alpha-1-antitrypsin (AAT) is the prototypical member of the serin protease inhibitor (SERPIN) family. It is mainly produced by the liver, but can also be produced by monocytes, macrophages and alveolar epithelial cells. AAT is released in large amounts during the acute phase of inflammation and limits tissue damage due to its antiprotease activity. Anti-inflammatory effects independent of antiprotease function are currently investigated. AAT might also play a role during Bronchiolitis obliterans syndrome (BOS), the major cause of death of patients after lung transplantation, which limits survival rates to 53% after 5 years. Ischemia/reperfusion injury, acute rejection and respiratory infections are main risk factors for the development of BOS. Our group has recently developed a model for human BOS in rats. This model consists of allogeneic left lung transplantation from Fischer 344 (F344) to Lewis (LEW) rats, a short course of immunosuppression followed by intratracheal instillation of lipopolysaccharide (LPS) 28 days after transplantation. Control allograft recipients were treated with vehicle. Isogeneic transplantation was performed in the LEW rat. We analyzed AAT mRNA expression by real-time RT-PCR in lung tissues of transplanted rats, as well as AAT protein expression by immunohistochemical staining on paraffin sections. Isogeneic transplantation provoked a graft-specific decrease in AAT mRNA-expression, which was transiently reverted upon LPS application. In allografts, however, the LPS-mediated increase in AAT expression was not observed. LPS-induced differences were also reflected in the intensity of the immunohistochemical staining of alveolar walls. Our results suggest that AAT supplementation early after lung transplantation might prevent chronic allograft rejection in the long run.

55 Modeling Cystic Fibrosis in vitro: A new possible platform for patient customised drug screening and ex-vivo gene therapy?

Haller R[1,2], Ulrich S[1,2], Weinreich S[1,2], Merkert S[1], Bednarski C[3], Mauritz C[1,2], Martin U[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover; [3]Centre for Chronic Immunodeficiencies, University Hospital Freiburg, Germany
DOI: 10.1055/s-0034-1376824

Cystic fibrosis (CF) is the most common lethal monogenic recessive disease in the caucasian population. Over 1900 mutations are known in the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) gene, but the most common mutation is the F508del resulting in misfolding of the CFTR protein. Until today, classical gene therapy trials have not been successful in CF patients, and currently approved CFTR modulators are only effective in a minority of CF patients. In contrast, stem cell-based approaches offer new perspectives for diseases like CF. Besides their almost unlimited proliferation and differentiation potential, human induced pluripotent stem cells (hiPSCs) can easily undergo genetic modification. Thus, patient-derived hiPSCs represent a suitable cell source for autologous ex-vivo gene therapy approaches to cure CF. In addition to cell replacement therapies, these cells might serve as a basis for patient-specific drug and toxicology screenings of CFTR modulators in vitro. Our strategy comprises the establishment of patient-specific hiPSCs, the targeted ex-vivo correction of individual CFTR mutations and the differentiation of the iPSCs into CFTR expressing cells. Generation of hiPSCs from somatic cells of CF patients was already successful and genetic correction of these mutated iPSCs was performed by two different gene targeting strategies based on homologous recombination

via Zinc-Finger- or TAL-effector nucleases. For proof of concept, we are aiming at the differentiation of non-disease specific human embryonic stem cells (ECS, as control) and of uncorrected and corrected CF hiPSCs into CFTR expressing cells. During differentiation of the hESC line, increasing levels of CFTR mRNA and of mature CFTR protein were detectable. CFTR mRNA expression was verified in differentiating non-corrected and gene-corrected CF hiPSCs as well. Current work is focused on the generation of CFTR reporter cell lines, facilitating monitoring of CFTR expression, optimisation of the differentiation protocol and characterisation of the CFTR positive cells.

56 Miniaturization of the Organ Care System® into rat lungs for the establishment of ex-vivo therapy

Wiegmann B[1,2], Jonidgk D[1,2], Maegel L[1], Braubach P[1], Höffler K[1], Bachmann S[1], Weder J[1], Ciubutaro A[1], Haverich A[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376825

Objectives: The Organ Care System® (OCS) is a well-established system used in human lung transplantation, allowing for warm perfusion and ventilation of the donor lungs. Besides lung retrieval, this system therefore offers an innovative opportunity for clinical ex-vivo therapy of diseased lungs for different indications, e.g. tumor therapy. While the patient is on extracorporeal membrane oxygenation, the otherwise inoperable lungs can be treated in the OCS, followed by autotransplantation. For the development of ex-vivo therapy, a miniaturized OCS for small animals model was established. **Methods:** Wistar rats were euthanized (per group n = 5), the left lung was connected to the miniaturized OCS, while the right lung was stored on ice. The OCS lungs were ventilated and perfused at body temperature under continuous monitoring (e.g. pressure, blood gas analysis). Four different perfusion solutions were analyzed (Steen solution®± blood, OCS solution®± blood). Thereafter the lungs were processed histologically and examined pathologically (e.g. HE staining). **Results:** The miniaturized OCS worked technically faultless, in particular the perfusion and ventilation went well. For all perfusion solutions stable pH, pO2, pCO2, oncotic pressure and systemic pressure could be observed. The base excess has to be stabilized by application of sodium hydrogen carbonate using both perfusion solution combined with blood. Furthermore, the lactate increased in these two combined perfusion solutions until the end of the experiment up to 7.0 mmol/l, while the two others indicated lactate levels up to 1.0 mmol/l. Pathological work up revealed no significant morphological changes, except for focal atelectasis. There were no delimitable differences in between the examined groups. **Conclusions:** The miniaturized OCS is a reliably working system to establish the ex-vivo therapies for different indiations. As ex-vivo therapies may need to be applied for more than 4 hours, extended perfusion times and various perfusion solutions are currently investigated.

57 Respiratory epithelial cells generated from human pluripotent stem cells – new therapeutic approach for (genetic) lung diseases

Ulrich S[1,2], Haller R[1,2], Weinreich S[1,2], Menke S[1,2], Mauritz C[1,2], Martin U[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376826

The in vitro production of respiratory epithelial (progenitor) cells from human pluripotent stem cells (hPSCs) offers promising new options for the treatment of respiratory diseases. Importantly, efficient technologies for targeted gene correction, based on e.g. zinc finger nucleases (ZFNs) or transcription activator like effector nucleases (TALENs), makes the hPSC-based treatment of genetic lung diseases like cystic fibrosis (CF) and surfactant deficiencies feasible. A prerequisite for such approaches is an efficient and robust differentiation strategy for the in vitro generation of the desired respiratory epithelial cell types. We therefore aim at the differentiation of human embryonic (hESCs) as well as human induced pluripotent stem cells (hiPSCs) into respiratory epithelial cell types. To evaluate the earliest respiratory differentiation steps, we make use of the hES3 NKX2.1-GFP (kindly provided by the lab of A. Elefanty) expressing eGFP under the endogenous promoter of NK2 homeobox 1 transcription factor (NKX2.1), known as the earliest marker in lung development. With our current serum-free monolayer-based differentiation strategy we receive about 70% definitive endoderm as the first developmental step. Via subsequent anteriorization, FOXA2+/SOX2+ anterior foregut endoderm was induced giving rise to about 15% NKX2.1-eGFP+ cells. Coexpression of NKX2.1-eGFP with the endodermal marker FOXA2 as well as qRT-PCR analysis indicate a respiratory phenotype of the NKX2.1-eGFP+ cells most likely excluding relation of the NKX2.1 expression to a neuronal or thyroidal cell fate. Additionally, a subset of the NKX2.1-eGFP+ cells coexpressed SOX2 demonstrating specification towards a proximal airway progenitor cell phenotype. In summary, first steps have been made towards the efficient generation of NKX2.1+ respiratory epithelial progenitor cells. Future work will focus on further optimization of the differentiation strategy and maturation of the cells with regard to cell replacement therapies as well as for disease modeling, drug screening and toxicity tests in vitro.

58 Developing a score of early postoperative regulatory T cell frequency to predict bronchiolitis obliterans syndrome-free survival at two years after lung transplantation

Salman J[1], Knöfel AK[1,4], Sommer W[1,4], Böthig D[2], Tudorache I[1], Avsar M[1], Ius F[1], Jansson K[1,4], Gottlieb J[3,4], Welte T[3,4], Haverich A[1,4], Warnecke G[1,4]
[1]HTTG, Hannover Medical School, Hannover; [2]Paediatric Cardiology, Hannover Medical School, Hannover; [3]Department of Pneumology, Hannover Medical School, Hannover; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376827

Introduction: Regulatory T cells (Treg) have potential to regulate alloantigens and thus may counteract the development of chronic rejection (i.e. bronchiolitis obliterans syndrome, BOS) in lung transplantation. BOS may affect over 60% of lung transplant recipients within five years. Here, we analyzed Tregs in peripheral blood of 120 lung recipients prospectively during the first 2 years and correlated with the onset of BOS at two years. **Materials and Methods:** In this study we detected circulating Treg by flow cytrometry in consecutive routine lung transplant recipients before transplantation 3 weeks, 3, 6, 12, 18 and 24 months after transplantation. Treg were defined as CD4+CD25high T cells and were further analyzed for relevant surface as well as intracellular markers such as, amongst others, CTLA4, CD127, FoxP3 and IL-2. Spirometry at 3 weeks, 3, 6, 12, 18 and 24 months after transplantation as well as protocol biopsy results were analyzed. We defined two groups by the development of BOS stage 1 or higher versus BOS stage 0 at two years. **Results:** A total of 120 consecutive patients were included into the study. While 97 patients showed a stable clinical course after lung transplantation, 23 patients developed BOS stage 1 or higher within the first 2 years after lung transplantation. As soon as 3 weeks after lung transplantation not only a statistically significant positive correlation could be detected between the frequencies of Tregs and the absence of BOS ($p < 0.05$), we also built a score defining a cut off value composed of IL2+/CTLA4+/CD127low and FoxP3+ Treg in peripheral blood at 3 weeks, predicting the probability of BOS development. **Conclusions:** Higher frequencies of Treg early after lung transplantation are associated with protection against development of BOS and they may thus have an early predictive function for the ensuing course following transplantation.

59 hiPSC derived endothelial cell types from scalable cultures for biofunctionalization and tissue engineering

Olmer R[1,3], Szepes M[1], Becker S[2,4], Gruh I[1], Martin U[1,3]
[1]Hannover Medical School, Leibniz Research Laboratories for Biotechnology and Artificial Organs (LEBAO), Hannover; [2]Max Planck Institute for Heart and Lung Research, Department of Lung Development and Remodeling, Bad Nauheim; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [4]Universities of Gießen and Marburg Lung Center (UGMLC), Members of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376828

Applications like full endothelialisation of gas exchange membranes in extracorporal membrane oxygenation (ECMO) devices for improved hematocompatibility, cell therapy of pulmonary hypertrophy or tissue engineering require large numbers of (patient-specific) endothelial cells (ECs). The isolation of ECs from peripheral blood or explanted vessels is well established however especially cells from older individuals show a limited proliferation capacity. Patient specific ECs from pluripotent stem cells (hiPSCs) might be an alternative suitable cell source. The opportunity to generate large amounts of undifferentiated hiPSC in defined media under scalable conditions [1] allows for the generation of cell numbers in dimensions which are suitable for envisioned applications. By differentiation of these well monitored cell populations a virtually unlimited number of (autologous) ECs may become available for disease modelling, tissue engineering approaches and biofunctionalization of ECMO devices. The growth factors BMP4 and VEGFA as well as modulation of the WNT pathway were utilized for the differentiation of the scalable suspension cultures to endothelial cell types. [2] Differentiation approaches resulted in up to 31% of CD 144 positive (VEcadherin) and 10% CD 144 and CD 31 double positive cells on day 14 of differentiation. FACS-sorted CD 31 positive iPSC derivatives will be characterized in detail with respect to their molecular phenotype, proliferative capacity and functionality. In addition, the generation of transgenic hiPSC reporter lines, which express a fluorescence reporter/antibiotic resistance under the control of EC specific promotors (VEcadherin or CD 31) for monitoring of differentiation and selection/purification of resulting cell types is in progress. Resulting patient- (and lung disease-) specific iPSC-derived ECs will represent a novel cell source for disease modelling or biofunctionalization of gas exchange membranes as well as for vascularisation of tissue engineered constructs. In addition, TALEN-based gene correction in iPSCs might enable novel concepts of ex vivo gene therapy for respiratory diseases. **References:** 1 Olmer, R., et al., Suspension culture of human pluripotent stem cells in controlled, stirred bioreactors. Disease Area: Lung Cancer

60 The influence of EGF/HGF signaling crosstalk on therapy resistance in NSCLC cell lines

Salopiata F[1], Hass H[2], Rauh D[3], Huber RM[4,5], Timmer J[2], Klingmüller U[1,6]
[1]German Cancer Research Center (DKFZ), Heidelberg; [2]University of Freiburg, Freiburg; [3]Technical University Dortmund, Dortmund; [4]Ludwig-Maximilians-University, Munich; [5]Comprehensive Pneumology Center München (CPC-M); [6]Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376829

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related deaths worldwide. Therapeutic treatment of NSCLC includes mainly chemotherapy due to high metastatic spread but recently also targeted therapy using epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKI) for patients with an EGFR-activating mutation. Although patients benefit from this treatment, the NSCLC cancer develops a resistance against EGFR TKI treatment and recovers after a few months. Besides the gatekeeper mutation T790 M in EGFR, the resistance can be mediated by hepatocyte growth factor (HGF) overexpression and amplification of its receptor c-Met. Yet, the mechanisms of this HGF mediated resistance are unknown. Besides EGFR-TKI resistance lung cancer patients can also develop a resistance against chemotherapeutics like cisplatin. This resistance is also speculated to be influenced by EGF and HGF signaling. Therefore cisplatin resistant cell lines were developed to investigate alterations in signaling occurring after cisplatin treatment. To obtain a deeper understanding of these mechanisms and provide improved therapeutic options, we analyzed c-Met and EGFR signal pathways MAPK and PI3K-Akt as well as their potential crosstalk in NSCLC cell lines. As model systems three cell lines with alterations in EGFR and c-Met mutation and expression status were selected to gain a broad insight in the individual cellular response. Time-resolved signaling data was acquired using quantitative immunoblotting. A systems biology approach and modeling based on ordinary differential equations will be applied to this data to describe the interaction of both ligands in a quantitative and time-resolved manner.

61 Individualisation of radiochemotherapy (RTCT) for locally advanced non-small cell lung cancer (NSCLC)

Tufman A[1,7], Borgmeier A[1,7], Belka C[1,7], Ulm K[2], Tian F[1,7], Flentje M[3], Schnabel P[4,8], Goldmann T[5,6], Huber RM[1,7]
[1]Department of Internal Medicine V, University of Munich, Munich; [2]Technical University Munich, Munich; [3]University of Würzburg, Würzburg; [4]University Clinic Heidelberg, Heidelberg; [5]Forschungszentrum Borstel, Borstel; [6]Airway Research Center North (ARCN), [7]Comprehensive Pneumology Center München (CPC-M); [8]Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376830

Background: Individualised therapy has not yet found its place in the treatment of stage III NSCLC. Although RTCT can be curative, many tumours progress despite multimodal treatment. The CTRT 99/97 Bronchial Carcinoma Therapy (BROCAT) study investigated radiotherapy (RT) vs. RTCT after induction chemotherapy. The German Intergroup Lung Trial (GILT) investigated consolidation CT following simultaneous RTCT. Here we present clinical and translational predictors of outcome in these two large randomised trials. **Methods:** We analysed histology subgroups within BROCAT, comparing adenocarcinoma, squamous cell and large cell tumours. We also examined site of first progression (PR), comparing local, central nervous system (CNS), and systemic PR. Within GILT we collected tumour biopsies and established a cooperation within the DZL to analyse potentially prognostic and predictive molecular markers. **Results:** BROCAT (n = 214) found longer progression free survival (PFS) with RTCT vs. RT after CT, and a trend to longer overall survival (OS). Site of first PR differed between the study arms ($p < 0.047$), with more CNS and distant metastases after RT (CNS 21%, distant 36%) vs. RTCT (CNS 7%, distant 24%), and more local and thoracic PRs after RTCT (55% vs. 34%). Histology in BROCAT: 59 adenocarcinoma, 171 squamous cell, 28 large cell, 10 mixed and 35 NSCLC not otherwise specified (NOS). There was a trend to longer OS in all histologies. Squamous cell carcinoma had longer PFS after RTCT, and large cell tumours showed a trend to shorter PFS after RTCT. The GILT trial (n = 279) found no significant OS benefit for consolidation CT after RTCT; however, some subgroups stood out. 27 samples from the GILT trial are being analysed for a panel of molecular markers. **Conclusion:** Further clinical and translational efforts are needed to increase our ability to tailor treatment to the patient and disease in stage III NSCLC.

DZL Imaging

62 Correlative three-dimensional observation of lung tissue by different tomographic methods

Hegermann J[1], Kühnel M[1], Kellner M[1], Wrede C[1], Ochs M[1]
[1]Institute of Functional and Applied Anatomy, Hannover Medical School, Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376831

Combining light- and electron optical methods on the same sample facilitates the understanding of organ structure by providing both overviews of large samples as well as high resolution insights into very small structural features. We present here the combination of Scanning Laser Optical Tomography (SLOT) with Electron Tomography (ET) to examine mouse lung tissue at low and high magnifications. SLOT allows to analyze, reconstruct and segment a whole mouse lung with a resolution

allowing the recognition of structures in size down to single alveoli. The resulting three-dimensional models allow for example the detailed analysis of the conductive blood and airway system architecture. Insights into subcellular regions are achieved with a resolution in the nanometre scale using ET. In lamellar bodies (the "surfactant" containing organelles in type II alveolar epithelial cells), single lipid lamellae can be observed.

63 T1-mapping magnetic resonance imaging for the detection of chronic lung allograft dysfunction – initial results

Renne J[1], Lauermann P[1], Hinrichs J[1], Schönfeld C[1], Sorrentino S[1], Gutberlet M[1], Jakob P[2], Haverich A[1], Warnecke G[1], Wacker F[1], Welte T[1], Gottlieb J[1], Vogel-Claussen J[1]
[1]Hannover Medical School, Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover; [2]University of Wuerzburg, Wuerzburg
DOI: 10.1055/s-0034-1376832

Background: Bronchiolitis obliterans syndrome (BOS) is the major limiting factor for long-term survival after lung transplantation, However, early markers for the detection are missing. **Aims and objectives:** T1 mapping MRI of the lungs is evaluated for the detection of chronic lung allograft dysfunction in patients following double-lung transplantation. **Methods:** Fifty-one double-lung allograft recipients were included and gave written informed consent. BOS was classified with spirometry and patients were divided into three groups: BOS 0, BOS 0 p and late stages (BOS 1 – 3). Coronal T1 maps of the lungs were acquired at room air and 100% oxygen using an inversion recovery snapshot fast low angle shot sequence at 1.5 T. The coefficient of variation for T1 values under room air as well under oxygen and the oxygen transfer function (OTF) were calculated. **Results:** The coefficient of variation for T1 values was significantly higher for BOS 1 – 3 patients on both the room air ($p = 0.007$) and the oxygen T1 maps ($p = 0.002$) compared to patients with BOS 0 status. The OTF showed a strong trend towards decreased values in the groups with increasing CLAD/BOS stages ($p = 0.07$). **Conclusions:** The heterogeneity of T1 values as well as the OTF may be used for early detection of BOS and should be evaluated in future prospective trials.

64 Surface modification of Carbon Black nanoparticles determine their cytotoxicity on mouse tracheal epithelial cells

Weinhold K[1], König P[1]
[1]Universität zu Lübeck, Airway Research Center North (ARCN), Member of the German Center for Lung Research, Luebeck
DOI: 10.1055/s-0034-1376833

Inhaled nanoparticles can deposit on the airway epithelium and affect the epithelial cells. We are interested in how the effects of nanoparticles on the airway epithelium are changed after surface modification regarding impairment of mucociliary clearance and epithelial cytotoxicity. We tested the following Carbon Black nanoparticles (CBNP) with similar hydrodynamic diameter: unmodified Printex®90 (CBNP/-), surface-modified Printex®90 with 9-nitroanthracene (CBNP/Na) or benzo[a]pyrene (CBNP/BaP) and an acetylene soot (A. soot). After incubation of mouse tracheae with 10 or 30 µg/ml CBNP for 24 h, their effect on cilia-driven particle transport, apoptosis and cell membrane damage, epithelial integrity and the mRNA expression of cytochrome oxidases (Cyp), mucins and cytokines were determined. CBNP/- attached to cilia and induce an increase of ciliary beat frequency (CBF) and mucus release. In areas with mucus, particle transport speed (PTS) was decreased but in areas without mucus, PTS was increased. The epithelium remained intact and mRNA expression of cytokines, mucins or Cyp was not increased. A. soot also led to an increase of CBF, whereas CBNP/Na and CBNP/BaP did not alter CBF. But all three modified nanoparticles caused a decrease of PTS based on induction of apoptosis and cell membrane perforation. Although epithelial cells were lost, the remaining epithelial cells preserved epithelial integrity. In addition, CBNP/Na, CBNP/BaP and A. soot induced mRNA expression of Cyp1a1 and Cyp1b1, but A. soot alone increased mRNA expression of MIP-2, KC, IL-6 and Muc5ac. Our results indicate that the acute toxicity of CBNP is determined by their surface modification and modified CBNP can impair mucociliary clearance.

65 Sudan Black B staining is a promising tool for secure localization of alveolar epithelial type II cells and automated proportionator sampling

Schneider JP[1], Mühlfeld C[1], Ochs M[1]
[1]Institute of Functional and Applied Anatomy, Hannover Medical School, Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376834

By means of stereology it is possible to quantify structural parameters within the lung, e.g. the total number of alveolar epithelial type II cells. When using the "density x reference space design" it is necessary to reduce shrinkage during histological processing, so that initial measurements of the total lung volume before processing still correspond to what is seen under the microscope after processing. We recently compared different types of fixation and embedding and found little shrinkage after primary glutaraldehyde/formaldehyde fixation, postfixation with osmium tetroxide and uranyl acetate and embedding in glycol methacrylate [2]. A proper type II cell quantification, furthermore, requires a secure identification of type II cells under the microscope. The latter, however, can make some difficulties in routine stainings. Therefore, more appropriate staining methods leading to good contrast between type II cells and the surrounding tissue are desirable. Selective immunohistochemistry might be impossible after our proposed method because of impairment of antigenicity by glutaraldehyde, osmium tetroxide or uranyl acetate. Lipid staining with Sudan Black B, however, is cheap, easy to apply in practice and perfectly compatible with our "low shrinkage processing protocol", because lipids (and therefore lamellar bodies) are well preserved during processing and then rather selectively stained by Sudan Black B. Additionally, it appears to be a well suited stain for automated detection of type II cells using the recently developed proportionator sampling [1]. Using thin sections, this approach may even be used for quantitative analysis of lamellar bodies at the light microscopic level. **References:** [1] Gardi J, Nyengaard J, Gundersen H. Automatic sampling for unbiased and efficient stereological estimation using the proportionator in biological studies. J Microsc 230: 108 – 120, 2008. [2] Schneider JP, Ochs M. Alterations of mouse lung tissue dimensions during processing for morphometry: A comparison of methods. Am J Physiol Lung Cell Mol Physiol. 306: L341-L350, 2014.

66 Imaging repair processes of small epithelial lesions in the mouse trachea after laser-induced injury

Kretschmer S[1], Pieper M[1], König P[1]
[1]Institut für Anatomie, Universität zu Lübeck, Airway Research Center North (ARCN), Member of the German Center for Lung Research, Luebeck
DOI: 10.1055/s-0034-1376835

Small lesions in the airway epithelium occur frequently and offer an entry for pathogens. Therefore injuries have to be repaired to prevent prolonged disruption of epithelial integrity and to maintain a normal airway function. The mechanism of the repair process of small lesions in the airways is largely unknown. To better understand this repair process of small lesions in the airways we used two-photon microscopy and an ex-vivo model of the mouse trachea. The explanted trachea was cut longitudinally and then imaged with the epithelium facing up. Epithelial lesions were induced by focussing Ti-sapphire femtosecond laser pulses to single epithelial cells for 1 – 8 seconds. Staining with propidium iodide (PI) allowed identification of damaged cells. Phalloidin was used to stain actin filaments after the experiment. Damaging of cells in a specific area of the epithelium was possible. Depending on the irradiation time an area of 1 – 12 epithelial cells was damaged. Hyperfluorescence around the beam focus and loss of autofluorescence in adjacent cells was observed. Within the lesion nuclei were stained with PI. Small lesions of 1 – 3 cells were closed within 2 – 3 h. Lesions of 4 – 6 cells needed 4 – 5 h or did not close within the observation time of up to 6 h. Epithelial cells around the lesion changed their shape by stretching. Especially the cells immediately adjacent to the wound margin protracted notably to close the lesion. During this process damaged cells were expelled apically into the lumen. Staining with phalloidin after two-photon microscopy showed a transepithelial actin ring formed in the cells around the wound which participate in closing the lesion. Healing of small lesions in the airways depends on an active coordinated movement of adjacent epithelial cells. Further studies will focus on the

molecular mechanisms of repair that might be impaired in airway diseases.

67 Improved Diagnosis of Pulmonary Emphysema using in vivo Dark-Field Radiography

Meinel F[1,5], Yaroshenko A[2], Hellbach K[1,5], Bech M[2], Nikolaou K[3,5], Eickelberg O[4,5], Reiser MF[3,5], Pfeiffer F[2], Önder Yildirim A[4,5]
[1]Institute for Clinical Radiology, Ludwig-Maximilians-University Hospital Munich, Munich; [2]Department of Physics and Institute of Medical Engineering, Technische Universität München, Garching,; [3]Institute for Clinical Radiology, Ludwig-Maximilians-University Hospital Munich, München; [4]Comprehensive Pneumology Center, Institute of Lung Biology and Disease, Helmholtz Zentrum München, Munich; [5]Comprehensive Pneumology Center München (CPC-M), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376836

Purpose: The purpose of this study was to assess whether the recently developed method of grating-based X-ray dark-field radiography can improve the diagnosis of pulmonary emphysema in vivo. **Materials and Methods:** Pulmonary emphysema was induced in female C57BL/6N mice using endotracheal instillation of porcine pancreatic elastase and confirmed by in-vivo pulmonary function tests, histopathology and quantitative morphometry. Mice were anesthetized but breathing freely during imaging. Experiments were performed using a prototype small-animal X-ray dark-field scanner that was operated at 35 kVp with an exposure time of 5 seconds for each of the 10 grating steps. Images were compared visually. For quantitative comparison of signal characteristics, regions of interest were placed in the upper, middle and lower zones of each lung. Receiver operating characteristic statistics were performed to compare the effectiveness of transmission and dark-field signal intensities and the combined parameter "normalized scatter" to differentiate between healthy and emphysematous lungs. **Results:** X-ray dark-field signal and normalized scatter were significantly different between mice with pulmonary emphysema and control mice and show good agreement with pulmonary function tests and quantitative histology. The sensitivity and specificity for identification of emphysema were 50.0% and 90.0% for the transmission signal, 96.7% and 73.3% for the dark-field signal and 96.7% and 96.7% for the combined parameter. **Conclusion:** X-ray dark-field radiography is technically feasible in vivo and provides a substantial diagnostic benefit over conventional transmission-based X-ray imaging.

68 DZL-Platform Biobanking

Ruppert C[1], Kuhn S[1], Bernemann I[2], Klopp N[2], Gaede K[3], Koch I[4], Lindner M[4], Anton G[4], Schnabel PA[5], Schneider M[5], Illig T[2], Muley T[5], Günther A[1]
[1]Universities of Gießen and Marburg Lung Center (UGMLC); [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [3]Airway Research Center North (ARCN); [4]Comprehensive Pneumology Center München (CPC-M); [5]Translational Lung Research Center Heidelberg (TLRC-H); Member of the German Center for Lung Research
DOI: 10.1055/s-0034-1376837

Broad, coordinated access to biomaterials is essential for the translation of research findings into patient therapies. A centrally-organized DZL Biobanking Platform will guarantee that member of the DZL as well as external partners will have easy and direct access to biomaterials from patients with pulmonary disease. The DZL Biobanking Platform will capitalize on existing biobanking structures within DZL sites and will be connected to the Technology and Methods Platform for Network Research in Medicine (TMF e.V.) and Biobanking and Biomolecular Resources Research Infrastructure (BBMRI) catalogues. The biomaterial banks of DZL sites are not homogeneous. They are varying regarding structure and organizational standards methods of biomaterial collection, sample, data and quality management. In addition to implementing the DZL Biobanking portal in order to provide an overview of existing collections and biomaterials, the DZL Biobanking initiative aims to harmonize operating procedures and policies across DZL sites. These harmonization efforts include standardization of informed consent procedures standardization of sample procurement, processing, and handling, as well as the development of harmonized of phenotyping tools and sample management. Member of the platform compiled a forward-looking broad informed consent form allowing for collection, unlimited storage, and unrestricted use of biomaterials and phenotyping data. For a prospective collection of biomaterials and phenotyping data an overarching data management structure was considered including a centralized patient registration and pseudonymization service and a data warehouse for integrating phenotyping, imaging an experimental data.

Pulmonary lipofibroblasts are thought to be involved in crucial aspects of lung physiology (development, regeneration, vitamin A storage, surfactant synthesis). Given the wide range of functions attributed to this cell type, the present study was designed to investigate the presence of lipofibroblasts in a variety of mammalian species (incl. man) and throughout postnatal development of mice, rats and humans. For this purpose, lung samples from 14 adult mammalian species (Etruscan shrew, mouse, rat, chinchilla, rabbit, dog, seal, goat, human, camel, lama, giraffe, horse and cattle) as well as from postnatal humans and neonatal, 6/7-day-old, 14-day-old and 42-day-old mice and rats were investigated using light and electron microscopic stereology. The volume fraction and the total volume of lipid bodies was estimated and related to the body mass of the animals. Among the adult animals, lipid bodies were only observed in rodents (mouse, rat and rabbit). In all other species, no lipofibroblasts were observed. Lipid body volume scaled with body mass with an expontent $b = 0.73$ in the power law equation. Throughout mouse and rat postnatal development, the volume of lipid bodies first increased, then declined and persisted at a lower level in the adult animals. We did not observe lipofibroblasts in the postnatal human lung. In conclusion, among 14 mammalian species lipofibroblasts were only observed in rodents. The great increase in lipid body volume during early postnatal development of the mouse lung confirms the special role of lipofibroblasts during rodent lung development and regeneration. It is evident that the cellular functions of lipofibroblasts cannot be transferred easily from rodents to other species.

70 Bronchiectasis-Associated Hospitalizations in Germany, 2005 – 2011: A Population-Based Study of Disease Burden and Trends

Ringshausen FC[1,6], de Roux A[2], Pletz MW[3], Hämäläinen N[4], Welte T[1,6], Rademacher J[1]
[1]Hannover Medical School, Hannover; [2]Center for Respiratory Medicine at the Charlottenburg Castle, Berlin; [3]Jena University Hospital, Jena; [4]Institute for Lung Research, Berlin; [6]Biomedical Research in Endstage and Obstructive Lung Disease (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376839

Background: Representative population-based data on the epidemiology of bronchiectasis in Germany are lacking. The aim of the present study was to investigate the current burden and the trends of bronchiectasis-associated hospitalizations and associated conditions in Germany in order to inform patient care and facilitate the allocation of healthcare resources. **Methods:** The nationwide diagnosis-related groups hospital statistics for the years 2005 – 2011 were used to identify hospitalizations with bronchiectasis as any hospital discharge diagnosis according to the International Classification of Diseases, 10th revision, code J47, (acquired) bronchiectasis. Poisson log-linear regression analysis was used to assess the significance of trends. In addition, the overall length of hospital stay (LOS) and the in-hospital mortality in comparison to the nationwide overall mortality due to bronchiectasis as the primary diagnosis was assessed. **Results:** Overall, 61,838 records with bronchiectasis were extracted from more than 125 million hospitalizations. The average annual age-adjusted rate for bronchiectasis as any diagnosis

was 9.4 hospitalizations per 100,000 population. Hospitalization rates increased significantly during the study period, with the highest rate of 39.4 hospitalizations per 100,000 population among men aged 75 – 84 years and the most pronounced average annual increases among females. Besides numerous bronchiectasis-associated conditions, chronic obstructive pulmonary disease (COPD) was most frequently found in up to 39.2% of hospitalizations with bronchiectasis as the primary diagnosis. The mean LOS was comparable to that for COPD (10.1 [95% CI 9.8 – 10.5] days). Overall, only 40% of bronchiectasis-associated deaths occurred inside the hospital. **Conclusions:** The present study provides evidence of a changing epidemiology and a steadily increasing prevalence of bronchiectasis-associated hospitalizations. Moreover, it confirms the diversity of bronchiectasis-associated conditions and the possible association between bronchiectasis and COPD. As the major burden of disease may be managed out-ofhospital, prospective patient registries are needed to establish the exact prevalence of bronchiectasis according to the specific underlying condition.

71 Modulation of immune-mediators from donor lungs using the OrganCareSystem® – a potential mechanism for improved outcome

Wiegmann B[1,2], Falk C[1], Müller B[1], Neudörfl C[1], Akhdar A[1], Kühn C[1,2], Tudorache I[1], Avsar M[1], Haverich A[1,2], Warnecke G[1,2],
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376840

Objectives: Release of donor-derived immune mediators (IM), triggering allorecognition and inflammation after transplantation (Tx), may impinge on clinical outcome using warm perfusion of donor lungs (OrganCareSystem®, OCS) or standard cold preservation (SOC). IM were analysed in preservation solutions (PS) and peripheral blood (PB), also clinical outcomes monitored. **Methods:** IM were quantified in PS and PB at protein level by multiplex-technology at the end of OCS (n = 12) or SOC (n = 9). Donor and recipient demographics and midterm outcomes were analysed. **Results:** PS concentrations of IL-6, IL-10, IL-16, IFN-g CXCL8, CCL4, Ang-2, PECAM-1 and PDGF-b were significantly higher in OCS than SOC ($p < 0.0001$). Inverse distribution was observed for FGF-b ($p = 0.005$). High concentrations in PS following OCS correlated with lower concentrations of IM in recipient PB after Tx. OCS vs. SOC median donor/recipient age was 45/55 vs. 46/56, underlying diagnoses: idiopathic/cystic fibrosis (n = 6/3 vs. n = 5/2), idiopathic pulmonary hypertension (n = 0 vs. n = 1) and emphysema (n = 3 vs. n = 1). No significant differences (minutes) of median cross clamp times for right (430 vs. 505) and left lung (569 vs. 641) were seen. Shorter median ICU-stay (3585 vs. 3750) and mechanical ventilation times (795 vs. 1051) were observed in OCS. Significantly higher % predicted FEV1 at discharge (FEV1) (71% vs. 55%, $p = 0.04$) and lower PGD-scores at T24 ($p = 0.28$) were seen in OCS. Six-month-survival was not different. Correlations between Ang-2 and IL-6 concentrations and FEV1, mechanical ventilation time, paO2/FiO2 and ICU-stay were identified. **Conclusion:** IM remained low in PS using SOC probably due to reduced metabolic activity in lung tissue during cold ischemia. During OCS preservation, significantly higher amounts of IM were released into PS which may represent depletion from the organ by accumulation. This 'dialysis' effect was associated with reduced inflammatory conditions after Tx, which had a positive impact on clinical outcome in OCS.

72 Genome-wide microarray-based screen for FOXJ1-dependent ciliary factors in the murine lung

Stauber M[1], Mai M[1], Lobschat K[1], Weidemann M[1], Schuster-Gossler K[1], Kellner M[2], Dittrich-Breiholz O[3], Kühnel MP[2], Gossler A[1]
[1]Institut für Molekularbiologie, Hannover Medical School, Hannover; [2]Institut für Funktionelle und Angewandte Anatomie, Hannover Medical School, Biomedical Research in Endstage and Obstructive Lung Disease (BREATH), Member of the German Center for Lung Research (DZL), Hannover; [3]Institut für Physiologische Chemie, Hannover Medical School, Hannover
DOI: 10.1055/s-0034-1376841

Ciliogenesis is crucial for proper organogenesis during mouse embryonic development and homoeostasis of adult tissues. A key regulator of motile cilium formation is the transcription factor FOXJ1 that directs ciliogenesis in various tissues including the respiratory epithelium of the lung and the ependymal epithelium of the brain. Downstream effectors of FOXJ1 are only partially known. In order to elucidate processes downstream of FOXJ1 that initiate ciliogenesis or enable cilium function, we conducted microarray screens comparing the murine transcriptomes of (1) Foxj1-deficient and wildtype lungs at embryonic day E16.5 and (2) unciliated and ciliated micro-dissected lung epithelia at embryonic day E14.5 and E18.5, respectively. We identified 180 genes deregulated in both screens including both already known regulators of ciliogenesis and novel factors that are now promising candidates for FOXJ1-dependent regulators of ciliogenesis. Many of those candidates exemplary tested by section in situ hybridisation of E18.5 mouse embryos to validate the microarray results are indeed predominantly expressed in the respiratory epithelium as well as in other ciliated tissues. Furthermore, several factors tested display subcellular localisation near the basal body of the cilium of monociliated IMCD3 cells implying ciliary importance. Currently, we analyse five of these candidates in more detail. For one of our candidates, 1700012B09Rik that is conserved between mouse and human and encodes a short protein of unknown function, we generated a knock-out mouse. We show that this gene is expressed in ciliated tissues including the embryonic node, the developing and adult lung and ependyma and that its expression depends on FOXJ1. The KO mouse neither reveals an apparent motile cilium defect nor a lung phenotype so that it is not yet clear whether 1700012B09Rik is involved in cilium formation or function and if so at what level.

73 The role of WNT/b-catenin signaling in smooth muscle cells during lung development and repair

Moiseenko A[1], El Agha E[1], MacKenzie B[1], De Langhe S[2], Bellusci S[1,3]
[1]Excellence Cluster Cardio Pulmonary System, Justus-Liebig-University Gießen, Gießen; [2]National Jewish Health, University of Colorado Denver, Denver, USA; [3]Universities of Gießen and Marburg Lung Center (UGMLC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376842

Wnt signaling is important for the formation of different organs during embryonic development. It also plays a key role in lung development, as it is required for branching morphogenesis, proliferation, differentiation and survival of lung progenitors in both the epithelium and mesenchyme. Upregulation of Wnt signaling in the mesenchymal cells is associated with lung pathologies, such as asthma, lung fibrosis, and pulmonary arterial hypertension. After naphthalene injury, an established mouse model of airway epithelial damage, the surviving ciliated airway epithelial cells express Wnt7b. Wnt7b then acts on parabronchial smooth muscle cells (PBSMCs) to induce Fibroblast Growth Factor 10 (Fgf10) expression leading to the expansion of epithelial progenitor cells required for epithelial restoration after injury. We will further investigate the role of Wnt signaling in PBSMCs (using the SMA-Cre-ERT2 mouse driver line, which we recently validated) by gain and loss of function approaches of Wnt signaling during development and in the context of naphthalene injury. Loss of function of Wnt signaling will be performed by using mouse lines that will allow specific deletion of β-catenin in smooth muscle cells. Gain of function will be performed by using mouse line, which allows expression of stable form of β-catenin in smooth muscle cells. We will also use different reporter lines that will allow us to visualize the smooth muscle cells which underwent Cre

activation (Tomatoflox/flox mice) and monitor Wnt signaling (Topgal and Axin2LacZ lines).

74 CILIA – Conditional immortalization of murine alveolar epithelial cells

Sapich S[1], May T[2], Carvalho C[3], Lehr CM[3], Wirth D[1]
[1]Helmholtz Centre for Infection Research, Braunschweig; [2]InScreenEX GmbH; [3]Helmholtz Institute for Pharmaceutical Research Saarland
DOI: 10.1055/s-0034-1376843

The blood-air barrier is formed by the alveolar epithelium of the peripheral lung consisting of mainly two cell types. The squamous alveolar epithelial type I cells (ATI) cover up to 97% of the total surface area and hence are responsible for the pulmonary gas exchange. However, alveolar epithelial type II cells (ATII) are cuboidal and undertake various functions including synthesis and secretion of surfactant, proliferative capacity and ion transport. Till date there is no murine cell line available that reflects the crucial barrier properties of primary ATI cells, which are functional tight junctions and as a consequence high transepithelial electrical resistance (TEER). The immortalization of alveolar epithelial cells could sustainably diminish the number of animal testing according to the 3R principle ("refine, reduce, replace") and provide the development of in vitro model systems which can be applied for drug delivery and pulmonary diseases studies. To overcome the laborious procedure of isolating primary cells and to enhance the reproducibility of in vitro test systems, we aim at the immortalization of alveolar epithelial cells from mice with different genetic background to generate novel cell lines mimicking the blood-air barrier. We established protocols for immortalization of primary murine alveolar epithelial cells (mAEpC). For this purpose, we lentivirally transduced bona fide immortalizing genes such as the simian virus large T antigen or a set of proliferation genes. Upon infection, cell lines could be established that exhibit a prolonged lifespan and show TEER values comparable with those of primary cells. Currently, these cells are characterized more detailed with respect to the expression of lung specific marker genes. These cell systems could allow standardized toxicity and transport studies for newly developed compounds and be helpful in elucidating infection pathways across the respiratory tract in the context of aerosol transmitted infectious diseases (e.g. swine flu, tuberculosis, etc.).

75 Tbx2 Controls Lung Growth by Direct Repression of the Cell Cycle Inhibitor Genes Cdkn1a and Cdkn1b

Lüdtke T[1], Farin H[1], Rudat C[1], Schuster-Gossler K[1], Petry M[1], Barnett P[2], Christoffels V[2], Kispert A[1]
[1]Hannover Medical School, Hannover; [2]Heart Failure Research Center, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands
DOI: 10.1055/s-0034-1376844

A considerable number of diseases in the mature lung can be related to the deregulation of (embryonic) programs that control the balance between proliferation and differentiation of cells. Pediatric pulmonary hypoplasia is a common cause of neonatal death; consequently, a lot of effort has been put into understanding the network of signaling pathways that assure correct lung growth and development. However the mechanisms of cell cycle control during lung organogenesis were only insufficiently understood. Unraveling these is crucial to understand how tissue homeostasis in the lung is achieved and how deregulation of the cell cycle may contribute to pulmonary diseases. We recently reported on the function of the T-box transcription factor gene Tbx2 in lung development. Tbx2-deficient mice exhibit markedly hypoplastic lungs in combination with reduced branching morphogenesis. Tbx2 mutant lungs feature decreased mesenchymal proliferation accompanied by excessive matrix deposition that indicates premature differentiation of fibroblasts. Downregulation of canonical Wnt-signaling and upregulation of the cell cycle inhibitors Cdkn1a (p21) and Cdkn1b (p27) precede these changes. Genetic depletion of Cdkn1a and Cdkn1b partially restored lung growth in Tbx2 mutant mice. In contrast, misexpression of Tbx2 in the lung mesenchyme of adult mice complementary resulted in hyperproliferation and a loss of Cdkn1a and Cdkn1b expression indicating a direct regulatory function of Tbx2 in control of these cell cycle regulators. We evaluated this presumption by ChIP experiments and showed binding of Tbx2 to the loci of Cdkn1a and Cdkn1b in vivo. **Conclusion:** Tbx2 regulates lung growth and mesenchymal differentiation by direct inhibition of Cdkn1a and Cdkn1b. Hence Tbx2 is a crucial mediator of cell cycle control during organ development in vivo. **References:** *DOI: 10.1371/journal.pgen.1003189*

76 Preclinical assessment of improved lentiviral vectors for gene and cell therapy of pulmonary alveolar proteinosis

Hetzel M[1], Lachmann N[1], Happle C[1,2], Kuhn A[1], Ackermann M[1], Brennig S[1], Schambach A[1], Hansen G[1,2], Moritz T[1]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL), Hannover
DOI: 10.1055/s-0034-1376845

Congenital pulmonary alveolar proteinosis (PAP) caused by mutations in GM-CSF receptor α chain (CSF2RA) represents a rare, life-threatening disease characterized by the accumulation of phospholipids and proteins in the lungs due to a functional insufficiency of alveolar macrophages. So far, therapy options are limited, but recent data suggest that a gene therapy approach based on the intratracheal application of gene-corrected macrophages may be feasible. To this aim, we have generated SIN-lentiviral constructs expressing the codon-optimized human CSF2RA-cDNA in combination with EGFP (Lv.EFS.CSF2RA.EGFP) or the inducible suicide gene iCaspase9 (Lv.EFS.CSF2RA.iCASP) from an EFS 1a-promoter sequence. BaF3 cells transduced with these vectors showed stable and longterm (> 3 month) expression of CSF2RA (CD 116) as detected by flow cytometry. Furthermore, these cells survived in an hGM-CSF dependant proliferation analysis even at low concentrations of GM-CSF (5 ng/ml) confirming the formation of functional hybrid receptors with the murine GM-CSF receptor ß-chain by the transgene. Further characterization of GM-CSF receptor downstream signalling revealed 5- to 6-fold increased STAT5 phosphorylation by Western blot analysis in response to hGM-CSF (over control cells). In addition, administration of a chemical inducer of dimerization (AP20187) to activate the iCaspase9 suicide switch led to time- and concentration dependent apoptosis of Lv.EFS.CSF2RA.iCASP transduced cells. Imposingly, conferring the vector to patient-derived CSF2RA-deficient CD 34+ cells rescued hGM-CSF dependent colony formation and allowed for effective granulocyte and monocyte differentiation. Furthermore, healthy CD 34+ samples transduced with the vector exhibited no aberrations in colony formation or in vitro differentiation towards macrophages analysed by surface marker expression of CD 11b, CD 68 and CD 163. Thus, we generated suitable vectors for a cell-based gene therapy approach for CSF2RA deficiency PAP, establishing functionality and safety in BaF3 as well as primary hematopoietic stem cells. Given its iCaspase9 safety switch in particular the CSF2RA.iCASP construct appears suitable for further evaluation towards first clinical approaches.

77 Generation of Clara cells from murine pluripotent stem cells – a new tool to explore airway epithelial regeneration

Katsirntaki K[1], Mauritz C[1,5], Schmeckebier S[1], Sgodda M[1], Puppe V[1], Eggenschwiler R[1], Duerr J[2], Schuber SC[2], Schmiedl A[1,5], Ochs M[1,5], Salwig I[3], Szibor M[4], Braus T[3], Cantz T[1], Mall MA[2,6], Martin U[1,5]
[1]Hannover Medical School, Hannover; [2]University of Heidelberg, Heidelberg; [3]Max-Planck-Institute for Heart and Lung Research, Bad Nauheim; [4]University of Helsinki, Helsinki, Denmark; [5]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH); [6]Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376846

Airway epithelial cell production in vitro offers new options to treat airway diseases, including genetic disorders like cystic fibrosis. Pluripotent stem cells (PSCs) (embryonic (ESCs) or induced pluripotent stem cells (iPSCs)) represent a suitable exogenous cell source for cell replacement strategies. Aiming at the long-term restoration of functional airway epithelium, epithelial progenitor/stem cells will be required, e.g. Clara cells. Clara cells are able to regenerate the airway epithelium following injury. With the aim to establish a mouse model of long-term airway epithelial regeneration, we aimed at the in vitro generation of Clara cells from murine PSCs. Using iPSCs established from two different

Clara cell reporter mouse strains enabled identification of generated Clara cells. iPSCs from CCSP-rtTA2 s-M2/GFP-tetO7-lacZ mice as well as ESCs were differentiated towards Clara cells using a serum-free monolayer (ML) protocol. The medium was supplemented with dexamethasone, 8-Bromo-cAMP and isobutylmethylxanthine (DCI), with or without keratinocyte growth factor (KGF). Specific marker expression was measured by qRT-PCR. iPSC-derived lacZpos Clara cells were visualized via X-gal staining and were further analyzed by electron microscopy. Pre-differentiated iPSCs were injected under the kidney capsule of immunodeficient mice and analyzed two weeks later. Furthermore, we established additional iPSC clones from CCSP-2A/YFP-2A/iCre knock-in mice. We have identified the factor combination DCI as an import inducer of the Clara cell marker CCSP in differentiation cultures of murine PSCs. The CCSP-driven expression of lacZ enabled the monitoring of iPSC-derived Clara cells and the confirmation of the Clara cell phenotype in isolated lacZpos areas by enhanced CCSP mRNA expression and a Clara cell typical ultrastructure. Moreover, the iPSC-derived lacZpos cells formed epithelial-like structures in vivo with similarities to lacZpos airways of the Clara cell reporter mice. The recently established iPSC clones from CCSP-2A/YFP-2A/iCre knock-in mice were already successfully differentiated into YFPpos cells using the DCI supplemented ML protocol.

78 Congenital Pulmonary Alveolar Proteinosis iPS-derived hematopoietic progenitor cells (HPCs) reveal functional defects upon GM-CSF administration

Mucci A[1], Lachmann N[1], Happle C[2,4], Ackermann M[1], Glage S[3], Hansen G[1,4], Moritz T[1]
[1]Experimental Hematology – Hannover Medical School, Hannover; [2]Hannover Medical School, Hannover; [3]Pathology – Hannover Medical School, Hannover; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376847

Hereditary Pulmonary Alveolar Proteinosis (herPAP), caused by a mutation in the GM-CSF receptor β-chain (Csf2rb), is an extremely rare lung disease resulting from the inability of alveolar macrophages to clear the alveolar spaces from surfactant phospholipids. Since current treatment options are extremely limited, we here investigate the suitability of a gene therapy approach based on hematopoietic cells derived from induced pluripotent stem cells (iPSC). Studies were performed in a murine model for Csf2rb-deficiency (Csf2rb-/-). Therefore iPSCs were generated from lin- bone marrow cells of Csf2rb-/- mice utilizing lentiviral overexpression of the standard Yamanaka-factors OSKM. Generated PAP-iPSCs displayed all major pluripotency criteria such as SSEA-1 expression, alkaline phosphatase activity, endogenous Sox2, Oct4, Klf4, Nanog reactivation, as well as three germ layers differentiation capacity assessed by teratoma formation. Following an eight-day embryoid-body based differentiation protocol, the PAP-iPSCs gave rise to CD41+ hematopoietic progenitor cells (HPCs) that were capable to differentiate into granulocyte-, monocyte-, and erythrocyte-containing colonies comparable to HPCs derived from control iPSCs. However, upon differentiation with GM-CSF, PAP-iPSCs – in contrast to control iPSCs – were unable to form GM-type colonies, recapitulating the defect found in primary lin- bone marrow cells of Csf2rb-/- mice. Furthermore, the obtained HPCs form both control and PAP-iPSCs were differentiated into macrophage-like cells in the presence of M-CSF. iPSC-derived macrophages expressed CD45, CD11b and F4/80, exhibited typical chemokine secretion, and activated the transcription factor STAT5 in response to IL-3 and GM-CSF in a similar manner to bone marrow-derived macrophages. In summary, we generated murine Csf2rb-deficient iPSC lines, which upon hematopoietic differentiation recapitulated GM-CSF dependent functional defects characteristic of PAP. These cells – upon genetic correction – appear as a promising source to test future cell and gene therapy strategies.

79 Combined ultra highfield MRI and SPECT-CT are promising tools in interdisciplinary research on animal models of human lung diseases

Meier M[1], Bankstahl JP[1], Rodt T[1], Koestner W[1,2], Madrahimov N[1], Knöfel AK[1,2], Haverich A[1,2], Bengel FM[1], Wacker F[1,2], Bleich A[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376848

Animal models of lung disease have provided extraordinary information to understand human disease. They are powerful tools that enable the study of the mechanisms and natural history of such diseases. Nevertheless anatomic and immunologic differences between mice and humans mean that those models have limitations that must be considered when interpreting the results. Magnetic resonance imaging (MRI) is a promising tool especially for serial studies, because of the absence of ionizing radiation. The detailed representation of interstitial structures remains the strength of CT while SPECT-CT adds the functional and physiological aspects into a molecular imaging setup. The ongoing development of computed tomography, SPECT and magnetic resonance imaging has markedly improved the imaging of lung diseases. With the optimization of the technology new demands on the interdisciplinary collaboration come up. The well-known technical problems of lung MRI (low spatial resolution, motion artifacts, low signal-to-noise ratio of the lung parenchyma) have been reduced by recent technical advances. Concerning chronic infiltrations CT scanning remains the superior imaging modality due to the inferior spatial resolution of MRI. There are ongoing research projects involving the applied technology of MRI, biophysical measurements using MR e.g., combined T1 and T2 mapping using efficient imaging sequences, using radial scans with ultra short TE enabling the visualization of detailed lung structures without using expensive hyperpolarized helium techniques and the use of MR to longitudinally monitor tissue parameters. We are on the move in developing and using in-vivo ultra-high field MRI techniques in combination with SPECT-CT to study aspects of lung diseases and lung transplantation. The increased sensitivity and enhanced contrast mechanisms at these high magnetic field strengths in multimodal applications might provide insight into yet unsolved problems. Image: Lung Perfusion SPECT-CT in a Mouse (left) and Ultrashort TE MRI image of lung tissue (right)

80 Investigation of the effect of different flow rates on the cell viability of fresh carotid arteries in vitro

Morticelli L[1,3], Kalozoumis P[1,3], Jentsch J[2], Böer U[1], Wilhelmi M[1], Haverich A[1,3], Korossis S[1,3]
[1]Hannover Medical School, Hannover; [2]University of Twente, Twente, The Netherlands; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376849

Introduction: Peripheral arterial disease leads to the damage of the blood vessels, currently replaced with vascular grafts, which are not able to regenerate in vivo. Tissue engineered vascular substitutes using decellularised equine carotid artery (ECA) seeded with the patient's own cells and mechanically stimulated in vitro represent an attractive alternative. The aim of this study was to investigate the optimum hydrodynamic conditions for maintaining the viability of fresh ECA in vitro. **Methods:** ECAs were isolated and disinfected in antibiotics prior to loading in a bioreactor. The optimum duration of the antibi-otic treatment was assessed through MTT assay and sterility test at 30 min, 1hour and 2hours. 3D fluid-structure interaction (FSI) simulations, based on stress-strain data from ECAs, were conducted on LS-DYNA to determine the wall shear stresses (WSS) at two steady volume flow rates of 265 ml/min (physiological) and 132.5 ml/min. The samples were then cultured statically and dynamically at the above mentioned flow rates, for 1day, and assessed with MTT as-say, H&E stain and immunofluorescence using CD31. **Results:** The optimum time to disinfect the ECAs without affecting their viability was 1hour. The WSS for the physiological and half-physiological flow rates used was 5.6 and 2.9 Pa, respectively. These were rather larger than the physiological val-ues reported by experimental studies (2.5 – 5 Pa). The samples conditioned for 1 day at both flow rates showed signifi-cantly higher levels of viability compared to the samples cultured statically and to the negative control (decellu-

larised ECA). The histological and immunofluorescence analysis revealed the integrity of the ECM, for both the static and dy-namic samples, and the presence of endothelial cells. **Conclusion:** The results suggested that dynamic conditioning improves cells viability. This study provided the basis for optimising the culture of the cell-seeded carotid arteries in vitro to generate peripheral arterial-like tissue.

81 Development and characterization of a decellularised xenogeneic mitral valve scaffold

Granados M[1], Morticelli L[1,2], Yablonski P[1], Hilfiker A[1], Tudorache I[1], Cebotari S[1], Haverich A[1,2], Korossis S[1,2]
[1]Hannover Medical School, Hannover; [2]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Center for Lung Research (DZL)
DOI: 10.1055/s-0034-1376850

Introduction: Mitral valve regurgitation is the second most common cause of surgery of the heart valves. Current treatment options are imperfect, requiring re-operations or lifelong anticoagulation therapy. The aim of this work was to develop and characterize a decellularised mitral valve scaffold for mitral valve replacement. **Methods:** Mitral valves from 6 month old pigs were disinfected, placed in hypotonic buffer and treated with SDS and sodium de-oxycholate for 36 hours, followed by extensive washing and nucleic acid digestion. Radial sections comprising annulus, leaflets, chordae tendinae, and papillary muscle were analyzed histologically by H&E and DAPI, immunohistochemically by collagen IV, and by alpha-gal fluorescence staining. DNA was extracted from the annulus, anterior leaflet, and chordae, and quantified using a NanoDrop spectrophotometer. Sections of the treated leaflets were analyzed under transmission electron microscopy (TEM), whereas fresh and treated leaflet strips were subjected to uniaxial tensile loading to failure. **Results:** Following decellularisation, no cell nuclei were observed under H&E or DAPI. There was also no change in the presence of collagen IV. The treatment resulted in a significant decrease of alpha-gal. DNA content was significantly reduced compared to the native tissue. TEM showed cell-free decellularised tissue, with a conserved histoarchitecture. The decellularised tissue demonstrated a großly-maintained mechanical integrity. **Conclusion:** A protocol that effectively removed cells and DNA, whilst maintaining the native valve histoarchitecture and mechanical integrity was developed. Although some alpha-gal was still detectable after decellularisation, the reduction observed was encouraging. The presence of alpha-gal could potentially be overcome in the clinical setting by the use of alpha-gal knockout porcine tissue. However, analyzing the effect of decellularisation on alpha-gal in wild-type porcine tissue could provide an insight on whether other sugars, also potentially immunogenic, are removed. Future work will focus on optimizing the protocol in order to further decrease the alpha-gal content.

82 Generation of CF-patient derived iPS cells and efficient footprintless designer nuclease-based gene targeting

*Presenting author The ability to genetically modify human induced pluripotent stem cells (hiPSCs), including the correction of gene defects by means of homologous recombination (HR) is of great interest regarding their potential for ex vivo gene therapy, especially in terms of rare pulmonary diseases like Cystic Fibrosis (CF). Genetic engineering of hiPSCs via customized designer nucleases has been shown to be significantly more efficient than conventional gene targeting, but still typically depends on the introduction of additional genetic selection elements. For the generation of CF patient-specific iPS cells, endothelial cells from the peripheral blood or fibroblasts from skin biopsies of CF-patients were isolated and reprogrammed through lentiviral overexpression of pluripotency factors. The CF-iPS cells, homozygous for F508del mutation, morphologically resemble human embryonic stem cells, express pluripotency markers and could be differentiated in vitro into derivatives of all three germ layers. For gene targeting approaches we developed a protocol for the establishment of efficient non-viral and selection-independent gene targeting in hESCs and hiPSCs. The protocol was applied to target the endogenous safe harbour locus AAVS1. Here, by using ZFNs and TALENs, targeting efficiencies of up to 1.6% were demonstrated for one hESC and two hiPSC lines, and stable transgenic PSC lines were generated by FACSorting. The high targeting efficiencies obtained allowed for direct PCR screening of correctly targeted clones by applying TALENs together with short single stranded oligonucleotide donors without any pre-selection (Merkert et al.). Targeting the underlying genetic defect in our CF iPSCs revealed targeted integration of the missing base pairs, as demonstrated in cell pools. The establishment of single cell clones is currently ongoing. The established targeting protocol will enable footprint less gene correction and transgene-independent isolation of mutation-corrected CF-iPSC clones which will facilitate disease modelling, drug screening and, ultimately, the generation of clinically useful transgenic iPSC derivatives. **Reference:** Merkert, S., Wunderlich, S., Bednarski, C., Beier, J., Haase, A., Dreyer, A.-K., Schwanke, K., Meyer, J., Göhring, G., Cathomen, T., and Martin, U. 83 A novel mouse model for the investigation of adaptive immune responses upon de novo antigen expression in lung epithelial cells

Riehn M[1], Cebula M[1], Ochel A[1], Gaur P[1], Hauser H[1], Wirth D[1]

Upon infection, viral antigen presentation is accompanied with activation of innate immunity which shapes the adaptive immune response and in particular the T cell response. We aimed at developing a mouse model to induce immune mediated lung damage to better understand the mechanisms involved in lung regeneration. For this purpose, we mated SPCCre mice in which the CreERT2 recombinase is expressed in lung alveolar type II epithelial cells (Rock et al., 2011) to RosaOva transgenic mice (Sandhu et al., 2011). In the resulting double transgenic mice Tamoxifen induced Cre recombination results in de novo OVA expression in about 50% cells. We employed a reporter mouse model SPCCre x ROSALuc to monitor the time course of activation of the Cre recombinase specifically in vivo in lung. To evaluate the T cell response upon antigen expression, we generated SPCCre x ROSA Ova x OT-I mice. In this model, the intracellular neo-antigen Ova is induced in alveolar type II cells of the lung in presence of Ova antigen specific CD8 T cells (OT-I). Upon Tamoxifen mediated induction of antigen we observed massive infiltration of lymphocytes as documented by histological analysis. Interestingly, this T cell infiltration was transient, suggesting OT-I cell mediated destruction of alveolar type II cells followed by regeneration of lung tissue. These findings indicate the potential of the model to investigate T-cell response, antigen clearance and reconstitution of respiratory tissue independently of the innate immune induction in the full-fledged adaptive immune system. **References:** Rock, J. Introduction: Mitral valve regurgitation represents the second major valvular disorder in the western world, whereas current strategies for mitral valve reconstruction are imperfect. The aim of this study was to

develop a tissue engineered substitute for mitral valve leaflet reconstruction using acellular porcine pericardium seeded with porcine mesenchymal stem cells (pMSCs). **Methods:** Porcine pericardial scaffolds were decellularised as described previously. pMSCs were cultured on the mesothelial sur-face of the scaffolds (3 cm diameter) under static conditions, using 3 different cell densities (2 x 104, 1 x 105 and 2 x 105 cells/cm^2). The seeded scaffolds were analysed by scanning electron microscopy (SEM), H & E and live/dead staining at 1, 3 and 7 days. Following 3 days of static culture, samples seeded with 1 x 105 cells/cm^2 were cultured dynamically (10% strain) for 1 day in a biaxial strain bioreactor. Following dynamic conditioning, samples were assessed for cell viability with live/dead staining and MTT assay, and for extracellular matrix (ECM) integrity with H&E. **Results:** The optimum seeding density for acellular pericardial samples was 105 cells/cm^2. Samples seeded with this density and maintained statically for 3 days, prior to dynamic conditioning, showed the best cell penetration without a significant disruption in the ECM. Seeded samples conditioned dynamically for 1 day showed similar levels of viable cells to seeded samples cultured statically for 1 day. Cell alignment was also obvious in the dynamically conditioned samples. **Conclusion:** Acellular pericardium was shown to be an optimum material for cell repopulation. Reseeded scaffolds were viable after 1 day under 10% dynamic strain. This study provided the basis for optimising the mechano-stimulation of cell-seeded pericardial scaffolds in vitro in order to generate heart-valve like tissue.

85 Core/Shell electrospun fibers as biodegradable scaffolds for sustained drug delivery in Wound Healing applications

Repanas A[1], Zernetsch H[1], Glasmacher B[1]

DOI: 10.1055/s-0034-1376854

Aim: During the process of wound healing it is really important to keep the area safe from bacteria infections and treat possible inflammation incidents. Model antiseptic and anti-inflammatory agents can be encapsulated into a drug delivery carrier for combined treatment. Electrospinning (E-Spin) has been acknowledged as a versatile technique for the production of biodegradable fibrous scaffolds to encapsulate therapeutics for wound healing. **Methods:** Both single jet and coaxial jet E-Spin were used as a method to produce fibers. Polycaprolactone (PCL), Benzoin (BZ) and Acetyl Salicylic Acid (ASA) were dissolved in 99.8Vol.% 2,2,2-Trifluoroethanol (TFE) for the single jet E-Spin. For the coaxial jet E-Spin the same solution was used for the core while a solution of Polylactic acid (PLA) or PCL in the same solvent was used as the sheath solution. Morphology of the fibrous scaffolds as well as fiber diameter and pore size were examined by Scanning Electron Microscopy (SEM). After incubation in PBS and acetate buffer at 37 oC inside a water bath the absorbance was measured using a UV-Vis spectrophotometer to evaluate the cumulative release of the drugs and the release mechanism. **Results:** The coaxial approach resulted in fibers with an average diameter of 1.83 & 0.68 μm and an average pore size of 16.11 & 9.09 μm2 for BZ and ASA respectively. Furthermore, the amount of drug released in the first 8 hours was reduced from 65.1% to 11.65% for BZ and from 58.32% to 33.14% for ASA while the encapsulation efficiency increased from 87.5% to 97.1% for BZ and from 34.36% to 86.13% for ASA, in contrast to single jet electrospun fibers, following a Fickian diffusion in all cases. **Conclusions:** Biodegradable scaffolds from PCL core-shell fibers can be considered as promising drug delivery carriers for sustained release of antiseptic and anti-inflammatory agents in wound healing applications. **References:** A. 86 Chitosan/Polycaprolactone electrospun biodegradable scaffolds for Cardiovascular Tissue Engineering

Repanas A[1], Zernetsch H[1], Mavrilas D[2], Glasmacher B[1]
[1]Institute for Multiphase Processes, Leibniz University Hannover, Hannover; [2]Laboratory of Biomechanics & Biomedical Engineering, Mechanical Engineering & Aeronautics, University of Patras, Greece
DOI: 10.1055/s-0034-1376855

Introduction: Polycaprolactone (PCL) and chitosan (CS) are polymers with attractive properties (excellent biocompatibility & degradation). However their mechanical properties seperately do not satisfy the needs for cardiovascular tissue engineering. In the present work we aimed to optimize electrospinning parameters to obtain a flexible PCL/CS polymeric scaffold, with combined nano- and micro-fiber architecture and appropriate mechanical properties for cardiovascular tissue engineering in regenerative medicine. **Methods:** PCL and CS were dissolved in acetic acid (AAC) and 2,2,2-trifluroethanol (TFE) using different concentrations. Electrospinning was performed at a custom made apparatus, at room temperature. Morphology of the fibrous membranes were examined by SEM. Cyclic sinusoidal uniaxial mechanical tests were performed with an electroforce dynamic tensile testing system. Rectangular, 15 x 10 mm strips were cut and tested at 0 – 30% strain, 1 cycle/s, RT, dry conditions. The applied force and the local principal strain were monitored and stress/strain data was computed. Mechanical properties like Young's modulus (the elastic modulus at linear portion of stress/strain curve) was evaluated. For biophysical characterization FTIR spectroscopy and contact-angle studies were performed. **Results:** SEM observations showed a micro fibrous (2 μm) structure in PCL scaffolds and a combined nano/micro- (0.25 – 2 μm) arrangement in PCL/CS blend scaffolds. Young's modulus showed a significant drop from 25 MPa (PCL) to 5 – 6 MPa for AAC and 12 MPa for TFE with increasing CS concentration, (0 – 30% total strain). The hydrophillicity of the scaffolds was significantly higher with the addition of CS. **Discussion:** From preliminary results it seems that the concentration of CS plays an important role in structural appearance of electrospun PCL fibers. A combination of small porous nanofibers with a greater porous microfibers arrangement was obtained in polymer blends, suitable for potential cell seeding. Elastic modulus of polymer blends, especially in higher CS concentration, was close to properties measured in soft cardiovascular tissues. **References:** Szentivanyi A. et al.
